 - * High-momentum part ($q > p_F$) accounts for 20% nucleons .
 - * pn- SRC pairs dominate by factor of 20 as compared to **pp** and **nn** due to the tensor forces.
 - * Factorization $n(p_1, p_2) = C n_{c.m.}(k_{cm}) n_{rel}(q)$
 - * SRC are connected with neutrino-nucleus interaction, neutron stars structure, modification of the bound nucleon structure (**EMC effect**).

— CONCLUSION —

- Translationally-invariant shell model (TISM) applied for S_A^x and $n_{cm}(k_{cm})$ of the deuterons in the ^{12}C works reasonable well for the $^{12}C(p, pd)^{10}B$ reaction at 670 MeV with transition to the g.s. of ^{10}B (s^4p^6) and its excited states $E_B^* > 20$ MeV (s^2p^8).
- TISM can be applied to BM@N data on quasi-elastic knock-out of nucleon from SRC NN pairs from the ^{12}C in exclusive reaction $^{12}C + p \rightarrow p + p + N + ^{10}B$
- The corresponding formalism is developed in the plane-wave approximation taking into account relativistic effects in the $p+ <NN> \rightarrow p + N + N$ within the LFD approach.
- pp/pn ratio obtained within TISM is in agreement with the data.
- Observed in $^{12}C(e, epp)^{10}B$ S-wave $k_{c.m.}$ momentum distribution is a puzzle for TISM. Corresponding measurements of $^{12}C(p, pd)^{10}B$ at BM@N conditions for s^4p^6 and s^2p^8 will be very important.
