Analysis Off-Line

I. Maldonado

Transport of particles through detector produces several particles without polarization that decrease the mean value of polarization for each bin of impact parameter or centrality.

To Reconstruct the polarization (Branch: TPCKalman Track) Analysis Offline

How this effect can change the value of polarization for reconstructed data?

Do we need to compare with generated data to correct by efficiency and acceptance or there is another method?

Projections of polarization as a function of "centrality"

I want to compare the "y" projection of polarization P_y with $sin(\Psi_{EP} - \phi_p)$ keeping in mind that

$$P = rac{8}{\pi lpha_H} \left< \sin(\Psi_{EP} - \phi_P) \right>$$

where Ψ_{EP} is the true angle of the event plane given by the MCEventHeader, ϕ_p is the proton azimuthal angle and α the weak-decay asymmetry parameter. The reconstructed polarization is symmetrical and on average zero: \rightarrow polarization is not considered for the decay.

For the proton identification I use MC association

Polarization with $sin(\Psi_{FP} - \phi_p)$

With this distribution we can infer a zero polarization for PHSD, the same as UrQMD, The procedure requires to check the behaviour at values close to 1.

SUMMARY

Global Polarization analysis at MPD

- I. Maldonado
- Analyzed data
- Only generated data
- Generated data with detector effects (Branch: MCTrack)

To Reconstruc the polarizatior (Branch: TPCKalma TPCKalma Track)

Off-Line

- We have shown that decays of hyperons are isotropic, consistent with zero polarisation.
- Particles produced by interaction with detectors are not polarized and diminishes hyperon global polarization in ~ 40 %.
- We have a preliminary distribution with polarization related to the products of decay.
- We have to analyze the feasibility to reconstruct this generated polarization which needs to be studied carefully.
