

## «The study of radiation defects in heterostructured semiconductors after irradiation at the irradiation facility of the IBR2 research reactor»

*Wednesday 13 October 2021 16:00 (15 minutes)*

Heterostructures of high quality A<sub>3</sub>B<sub>5</sub> arsenides with a quantum well based on In-Ga<sub>1-y</sub>As exhibit high mobility of a two-dimensional electron gas and are actively used in microwave heterostructure electronics. In the heterostructures, the current-conducting layer is very thin —of the order of 10–20 nm, enclosed between wide-gap barriers; therefore, the radiation physics of such structures may differ from what was done in classical bulk semiconductors. A set of samples with heterostructures were irradiated in the irradiation unit of the IBR-2 research reactor. Preliminary results on x-ray diffraction and Raman spectroscopy are obtained.
