

**6th International Workshop
on Deep Learning in Computational Physics
(DLCP-2022)
July 7, 2022**

**Decomposition of Spectral Contour
into Gaussian Bands
using Gender Genetic Algorithms**

G.A. Kupriyanov, I.V. Isaev, S.A. Dolenko
Laboratory of Adaptive Methods of Data Analysis
D.V. Skobeltsyn Institute of Nuclear Physics,
M.V. Lomonosov Moscow State University

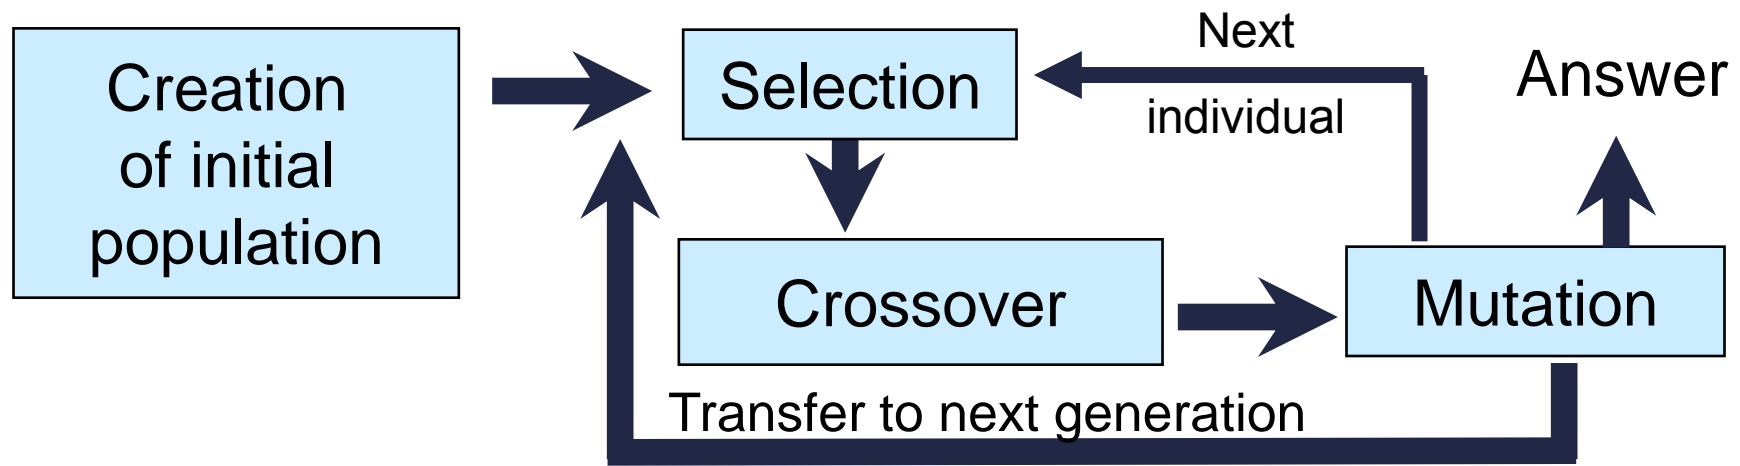

Genetic Algorithms (GA)

- An effective class of **optimization** algorithms based on ideas of **evolution** in nature
- A number (**population**) of candidate solutions (individuals) are considered **simultaneously**
- The quality of a solution is estimated by its **fitness function**
- Two basic **principles** applied are **selection** and **inheritance**
- **Selection** of the fittest provides survival of better individuals
- **Inheritance** brings information contained in selected individuals to next generations

Genetic Operators

Algorithm of computation

The **main aspects** of an implementation of GA are:

- **Type of coding** of information in an individual
- The method of **selection**
- The **crossover** operator providing inheritance and exchange of information between parents
- The **mutation** operator providing search of new areas

Conventional GA and Gender GA (GGA)

- In conventional GA, **all individuals are equal** in respect to genetic operators
- In nature, higher mammals use **sexual** selection
- The **female** gender is responsible for **preserving useful features** found by the evolution
- The **male** gender is responsible for **variability**. Among males, geniuses and freaks are more common than among females
- **In this study**, we divide the population in what we call GGA into males and females half by half
- The **mutation rate for males** is several fold higher
- The **females** have a limit on the number of **crossovers** N

Testing on 2D Model Functions: Func Types

H1

Ackley

Bohachevsky

Griewank

Rosenbrock

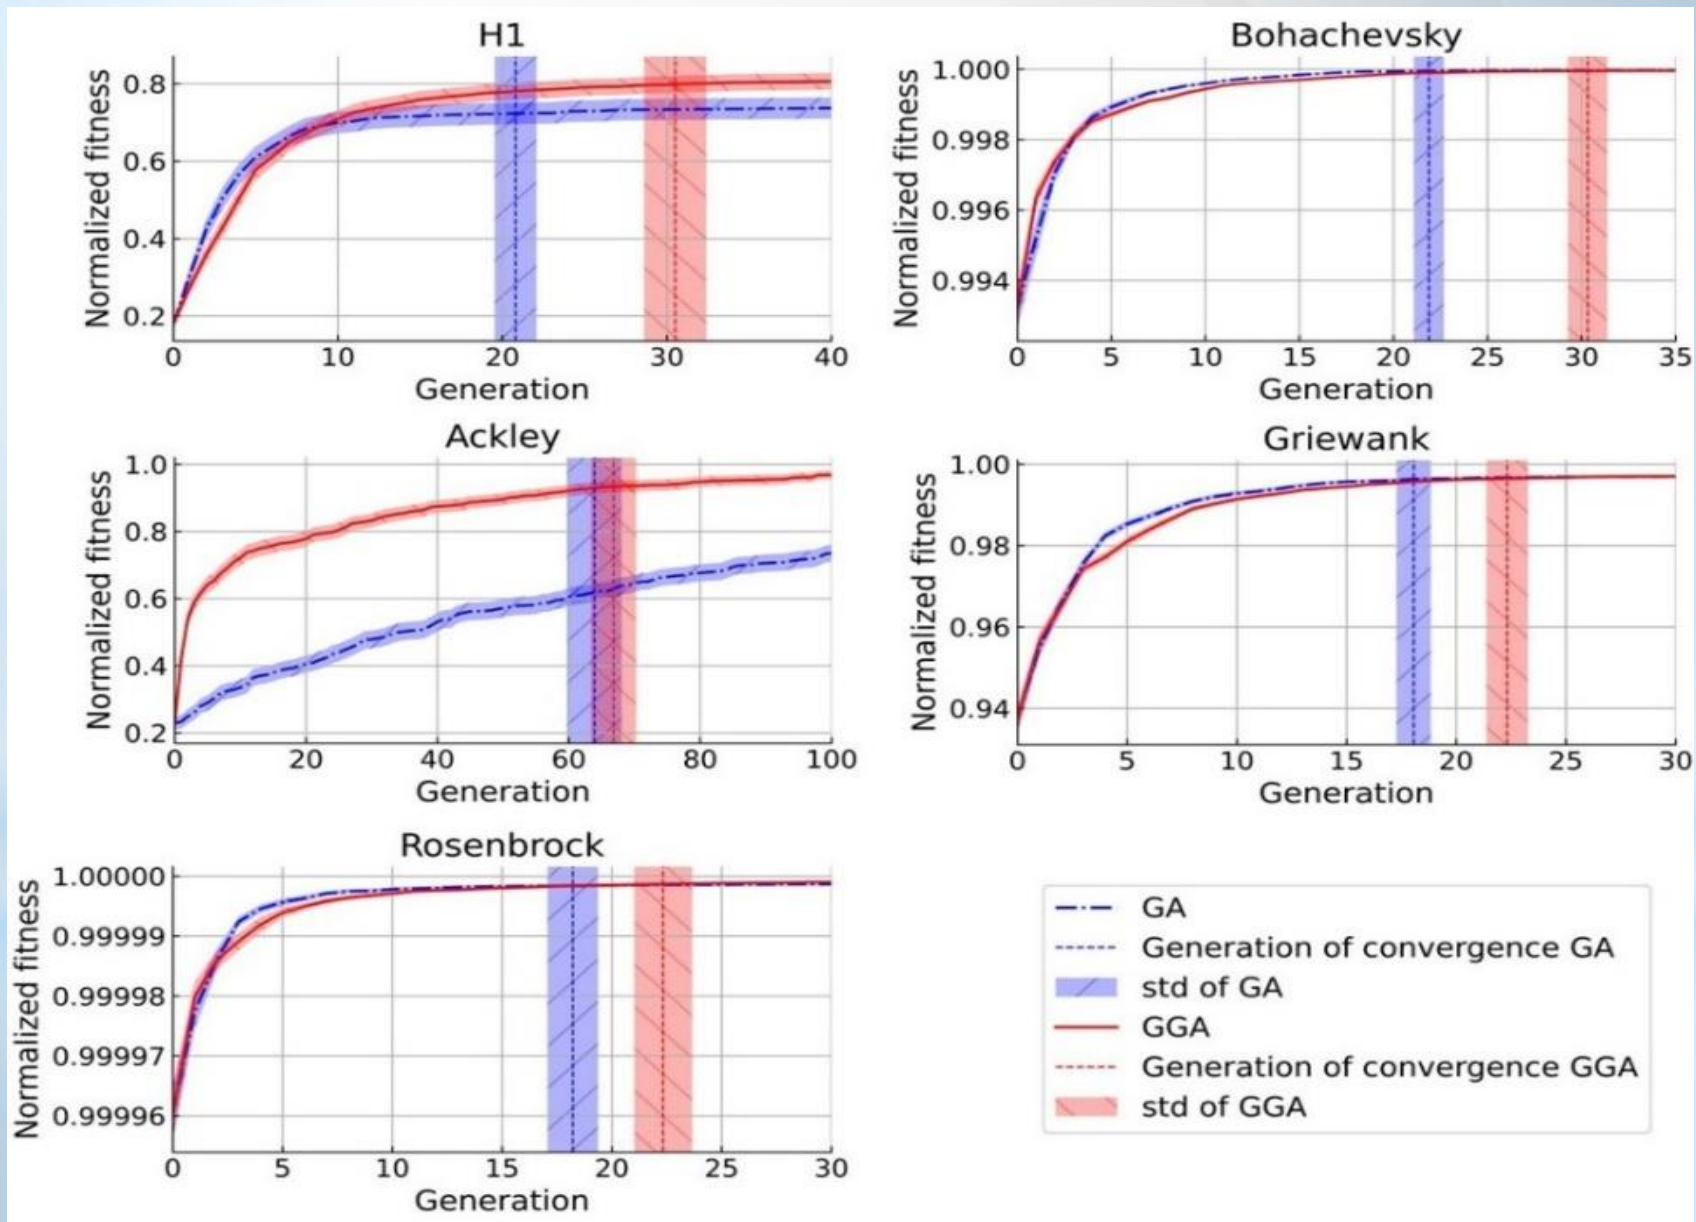

Testing on 2D Model Functions: Parameters

- **Stopping criterion:** less than 10^{-6} increase in fitness function maximum in the population during last 20 generations
- 100 **independent runs**
- Continuous chromosomes with **binary encoding**
- **Roulette wheel** selection method
- **Single-point** crossover operator
- **Single-bit** mutation operator
- **Fixed population size** in all generations
- Equal number of **males and females** in each generation

Testing on 2D Model Functions: Parameters

Parameters	GA	GGA
Dimension of chromosomes, bits	25	25
Individuals in the population	100	100
Share of elite individuals	6%	6%
Probability of mutation	1%	5% - males 0.1% - females
Maximum number of times each female may be selected	-	5

Testing on 2D Model Functions: Results

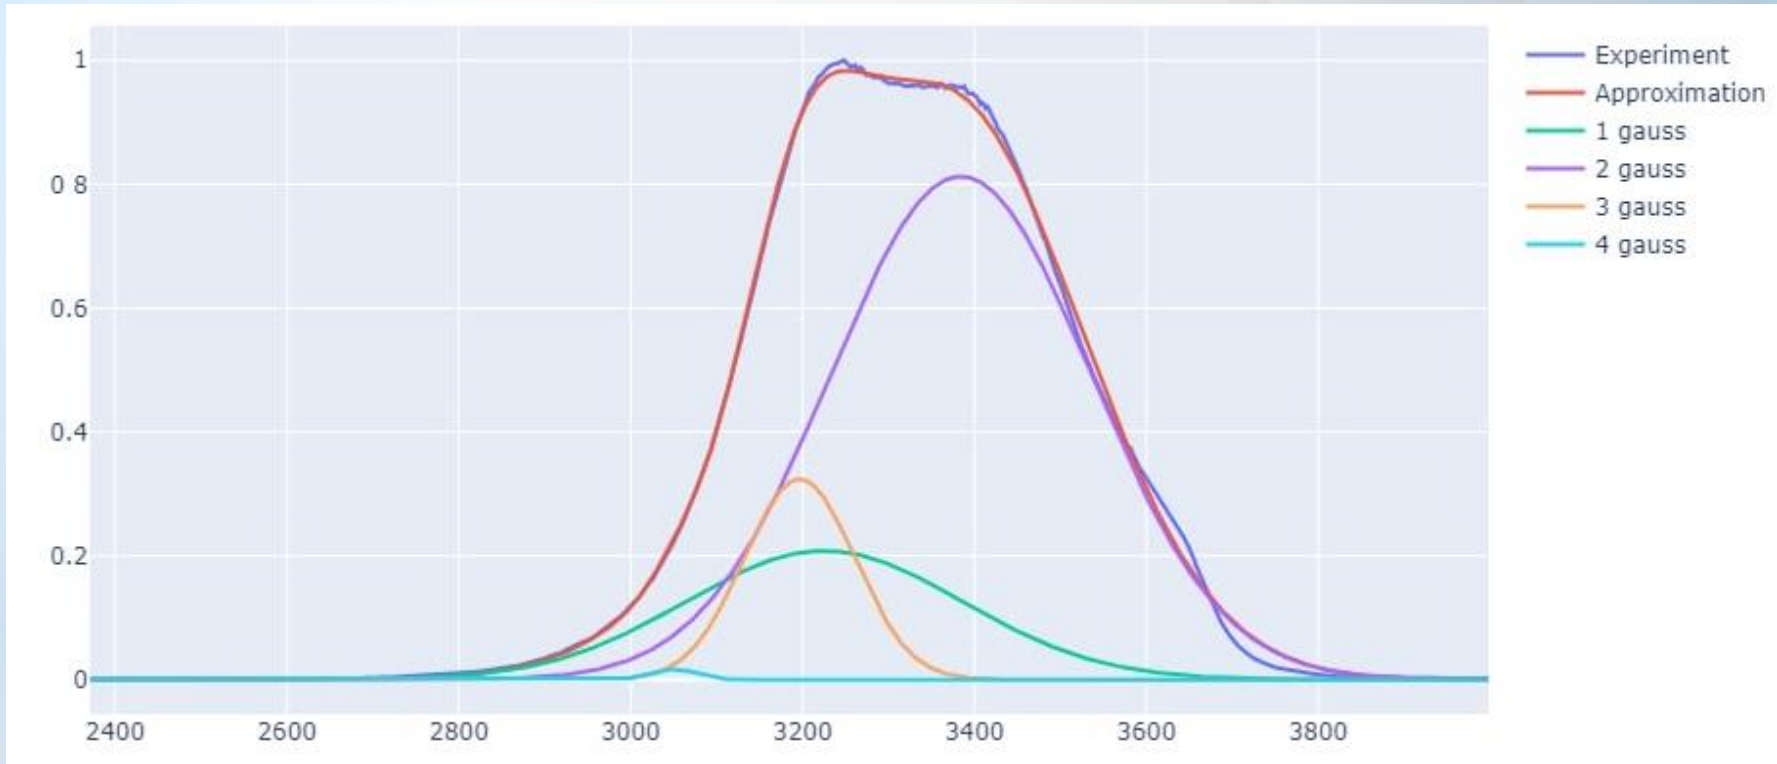

Dependence on the Number of Selections of a Female

- Starting from $N=3$, there is **no dependence**
- The **best results** are for the strongest limitation ($N=1$)

Decomposition of Spectral Contour

- Raman **valence band** of liquid water
- Decomposition of spectral contour into **Gaussian shapes**
- This is an **incorrect inverse problem** solved with various error values for various numbers of Gaussians
- 3 parameters per Gaussian; **multiple fitness minima**

Conclusion

- Gender modification of GA is **more efficient** than conventional GA for **complex multi-extremum** problems
- It prevents **premature degradation** of the population and stop of the evolution
- Strong **limitation on the number of crossovers** per female improves the results of optimization
- The algorithm has been tested on **several model problems** and on **one real-world problem**.

Further tests on a **wider variety** of problems are needed

- **Other differences** between genders may be introduced

Thank you for your attention!
