- мотивация и полученные результаты;
- работы и доклады на конференциях, выдвигаемые на конкурс ОИЯИ по разделу “научно-исследовательские экспериментальные работы”.

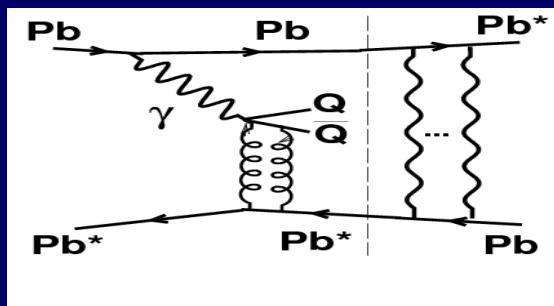

UPC of heavy ions

Ultra-peripheral collisions (UPC)

The LHC in heavy-ion mode → powerful source of quasi-real photons with intensity $\sim Z^2$.

Photon →
a vector meson (VM) →
scatter off a target
either coherently off whole nucleus (VM $p_T \sim 30$ MeV/c)
or incoherently off nucleons (VM $p_T \sim 300$ MeV/c).
NB there is bidirectional photon ambiguity in case of heavy ions

Large $Z \rightarrow$
huge photon fluxes →
UPC can be accompanied by another photon exchange →
EM nuclei excitation →
neutron emission detected in Zero Degree Calorimeters.

UPC studies address gluon shadowing in nuclei in photoproduction of vector mesons,
two-photon processes like light-by-light scattering, dilepton production etc.

A Large Ion Collider Experiment (ALICE) at LHC

THE ALICE DETECTOR

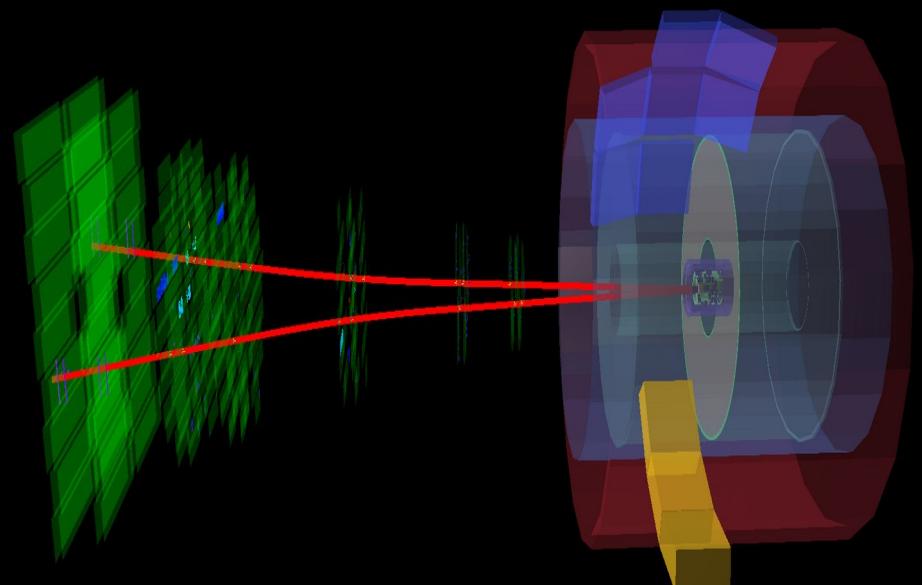

ALICE systems relevant for J/ψ / ρ^0 photoproduction measurements:

- Muon spectrometer (item 12 on scheme) /TPC (3) to reconstruct J/ψ or ρ^0 decays;
- Trigger detectors: ITS SPD (1), V0 (2), AD (17), TOF (5) and muon trigger chambers (14);
- Zero Degree Calorimeters (18) to detect neutrons from nucleus EM dissociation.

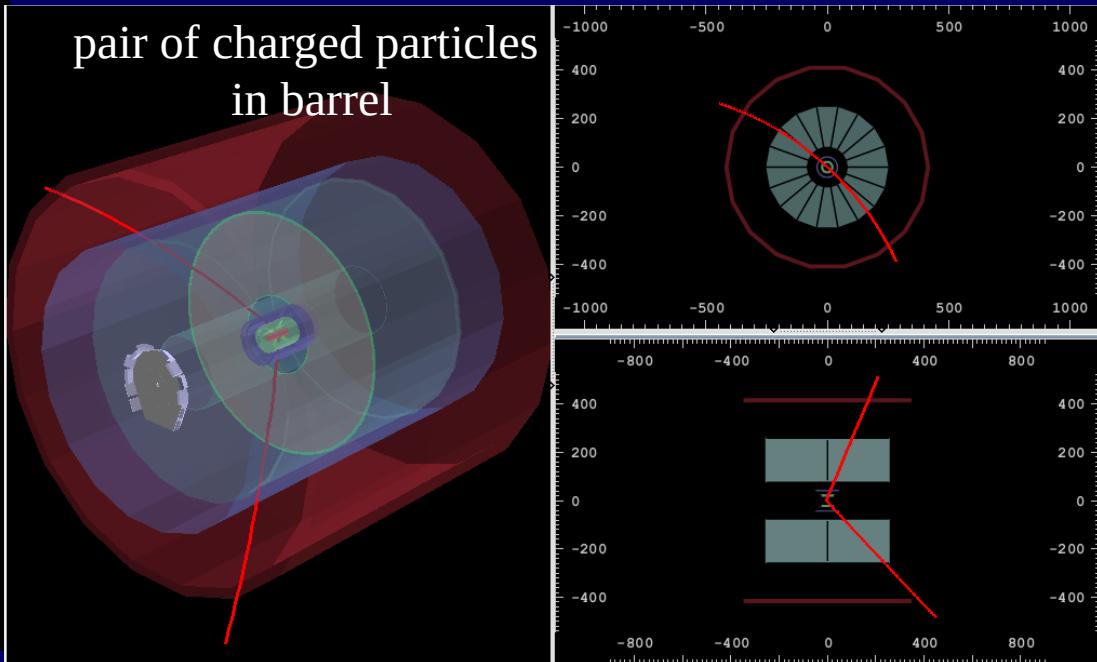

ALICE

forward dimuons

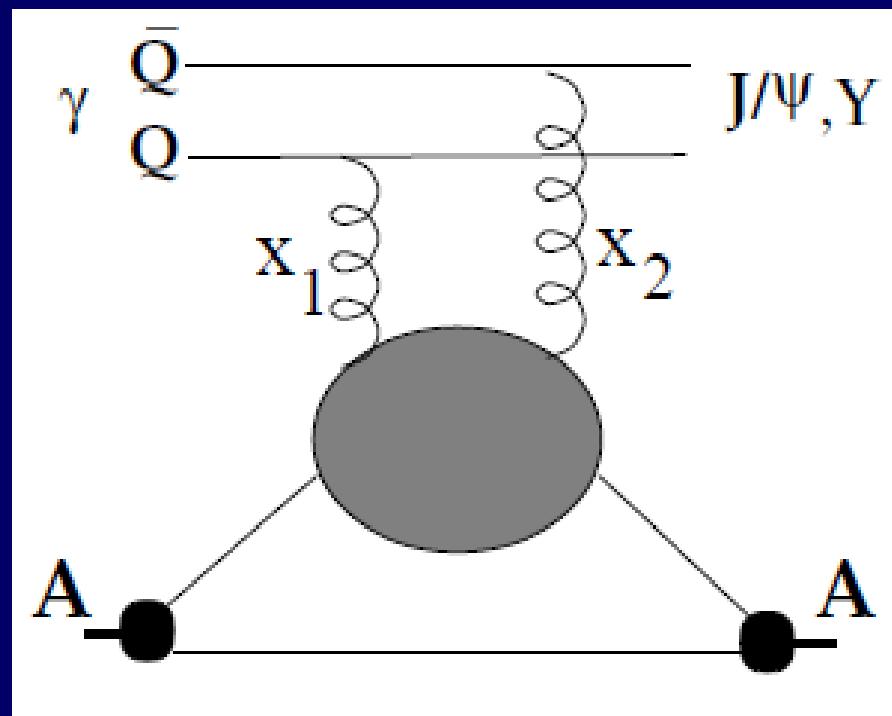

pair of charged particles
in barrel

Main features of UPC vector meson photoproduction:

- exclusive events, only vector meson decay particles detected;
- transverse momentum balance of final state particles.

Coherent J/ ψ photoproduction in UPC

Quarkonium photoproduction ($\gamma A \rightarrow J/\psi A$) at LHC probes high W_{vp} (small x) range.

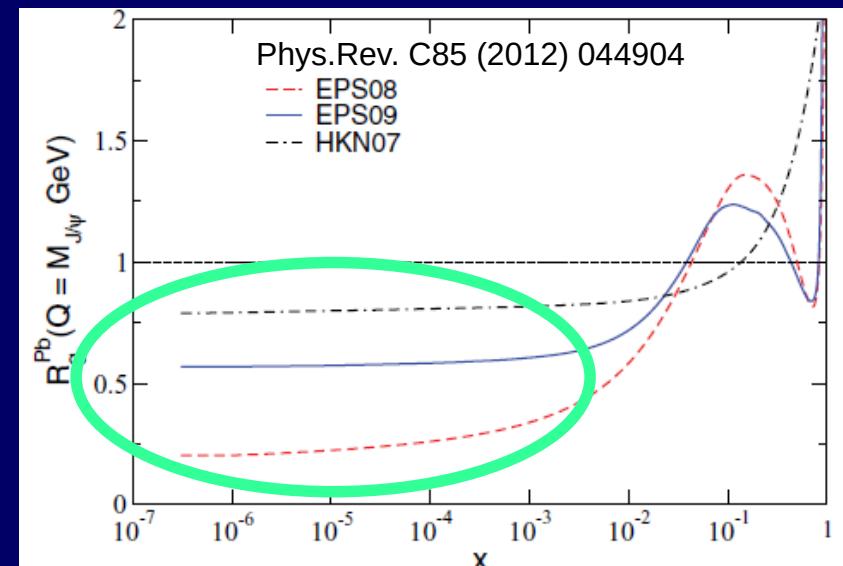

The leading order cross section
(assuming that gluons have \sim same x , i.e. $x_1 \approx x_2$)

$$\frac{d\sigma_{\gamma A \rightarrow J/\Psi A}}{dt} \Big|_{t=0} = \xi_{J/\Psi} \left(\frac{16\pi^3 \alpha_s^2 \Gamma_{l+l^-}}{3\alpha M_{J/\Psi}^5} \right) [x G_A(x, \mu^2)]^2$$

M. G. Ryskin, Z. Phys. C57 (1993), 89

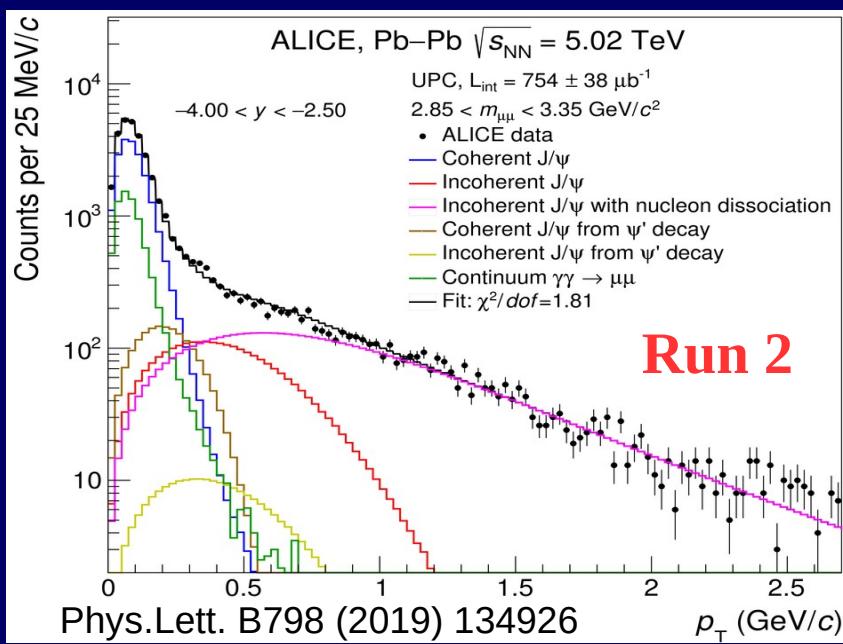

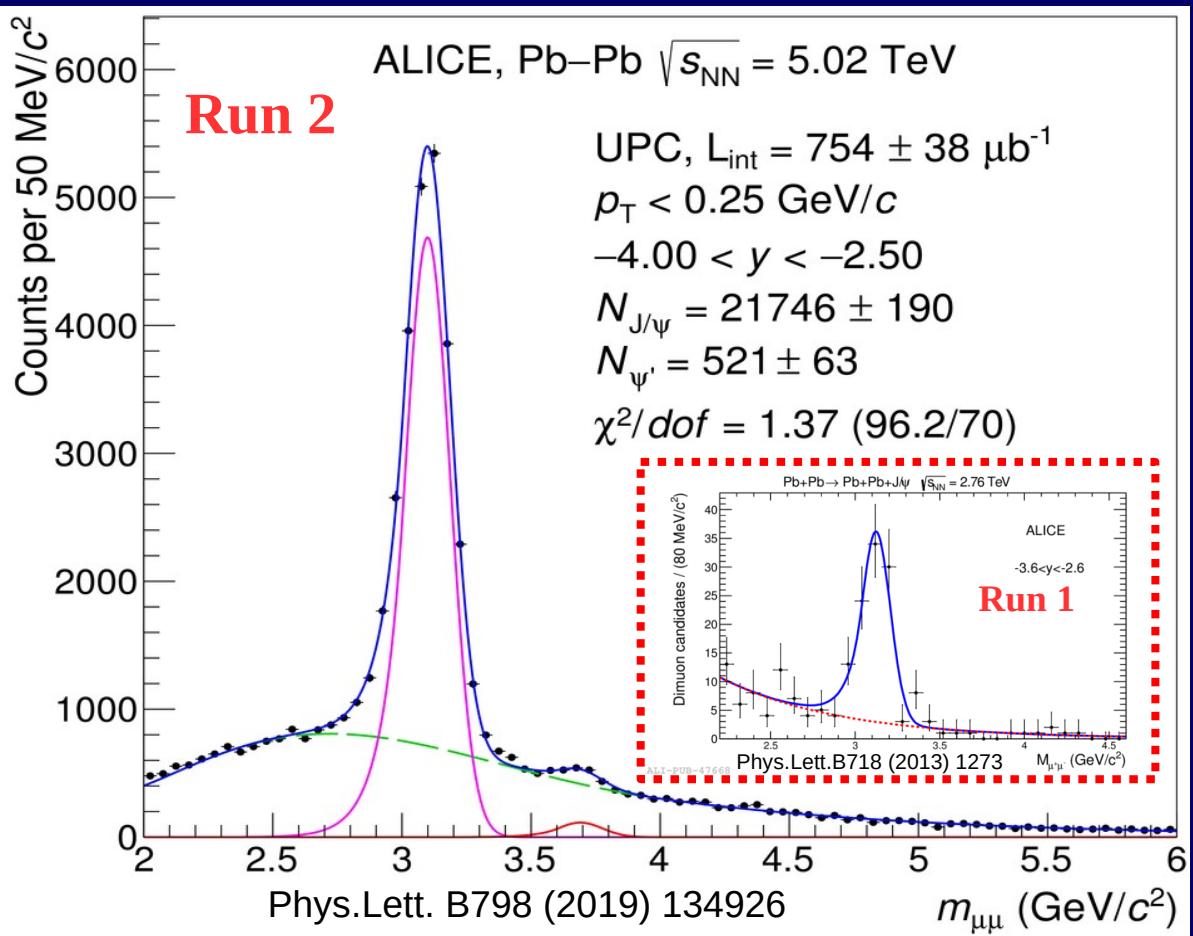

extensions of the calculations to NLO are discussed in
Flett CA, et al. arXiv:1912.09128 [hep-ph] (2019)

how to properly incorporate nuclear shadowing
at small x ?

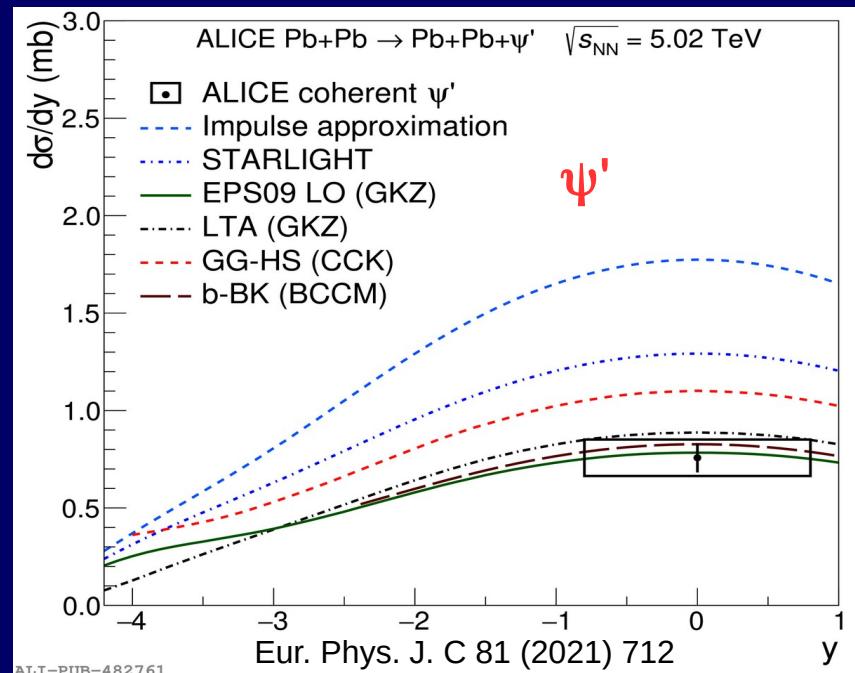

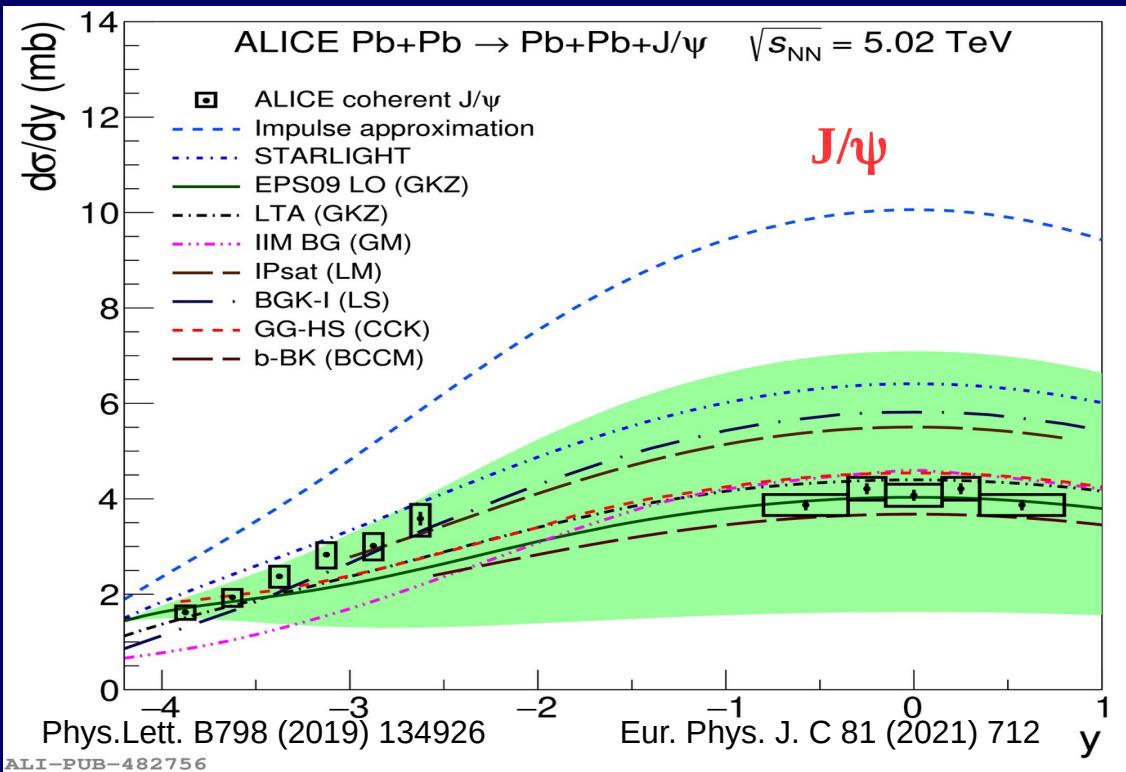

Increased LHC Run 2 Pb-Pb luminosity ($\int L > 700 \mu\text{b}^{-1}$), larger J/ ψ photoproduction cross section and more efficient event triggering provides ~ 200 times larger J/ ψ yield at forward rapidities as compared to the Run 1 data.

Forward AD detector installed for Run 2 and included into the trigger suppresses background from peripheral heavy-ion collisions.

Coherent production of J/ ψ and ψ' in Pb–Pb UPC

impulse approximation: no nuclear effects

Coherent production of J/ ψ at very low p_T in Pb–Pb UPC

The nuclear modification factor R_{AA} shows a large enhancement of the J/ ψ yield for $p_T < 0.3$ GeV wrt to expectations from hadronic production

This excess, which was previously seen in more peripheral collisions, is now confirmed for most of the total hadronic cross section down to at least a level of 30% in centrality.

Photoproduction of low- p_T J/ψ from peripheral to central Pb--Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV

Coherent ρ^0 production in Pb–Pb and Xe–Xe UPC with LHC Run 2 data

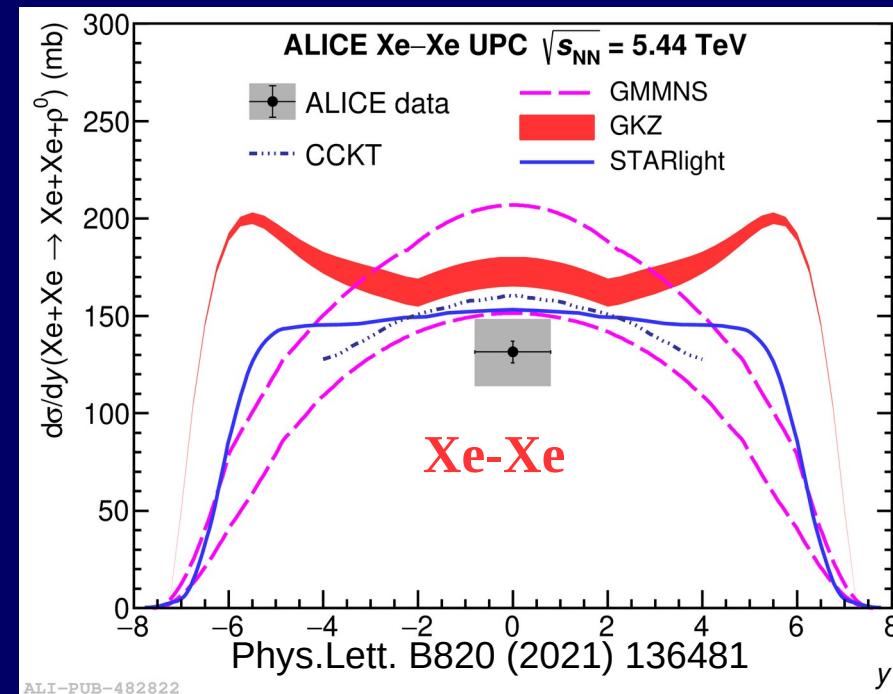

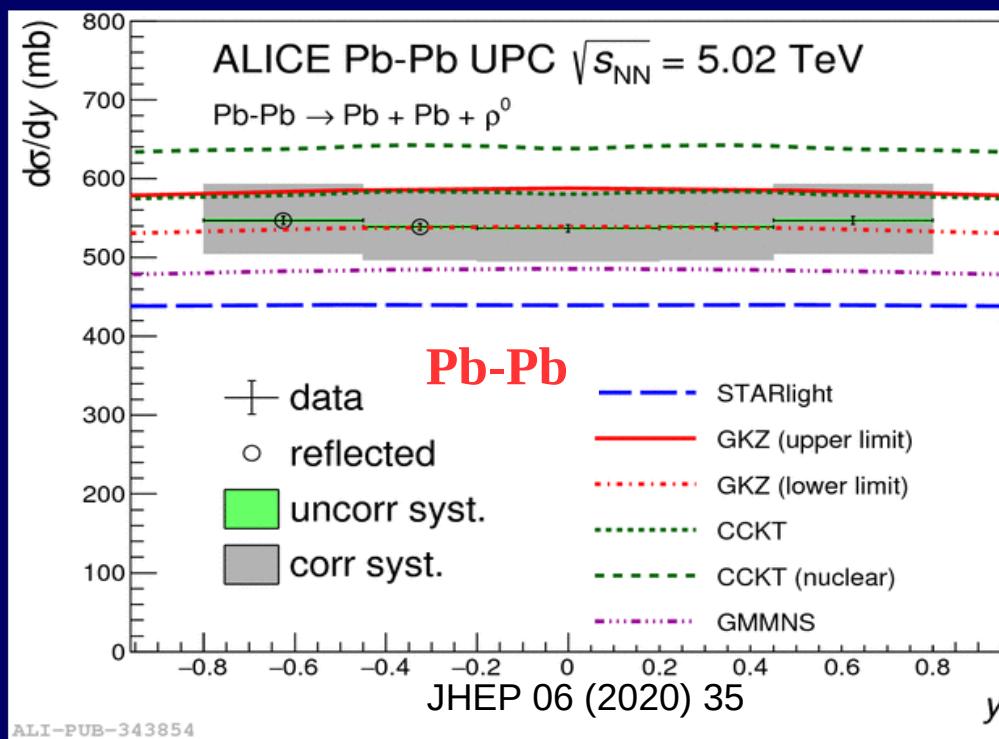

Photonuclear production of ρ^0 in heavy ion UPC at the LHC has a large cross section which makes it a good tool to study the approach to the black-disk limit of QCD.

The fit done by Breit-Wigner for resonance shape

- + constant term for direct pair production
- + interference between them
- + dimuons from $\gamma\gamma$ interactions.

Coherent ρ^0 production in Pb–Pb and Xe–Xe UPC with LHC Run 2 data

GKZ (V. Guzey, E. Kryshen and M. Zhalov, Phys. Rev. C93 (2016) 055206):

Vector Meson Dominance model + Gribov-Glauber model of nuclear shadowing for fluctuations of the photon-nucleons interaction;

CCKT (J. Cepila, J. G. Contreras, M. Krelina, and J.D. Tapiak Takaki, Nucl. Phys. B934 (2018) 330–340):

colour-dipole model + gluons “hot spots” of the structure of the nucleon in the transverse plane +Glauber model;

GMMNS (Goncalves, Machado, Morerira, Navarra and dos Santos, Phys. Rev. D96 (2017) 094027):

Iancu-Itakura-Munier (IIM) approach for gluon saturation + colour-dipole model;

STARLIGHT (S.Klein, J.Nystrand et al. Comp. Phys. Comm. 212 (2017) 258):

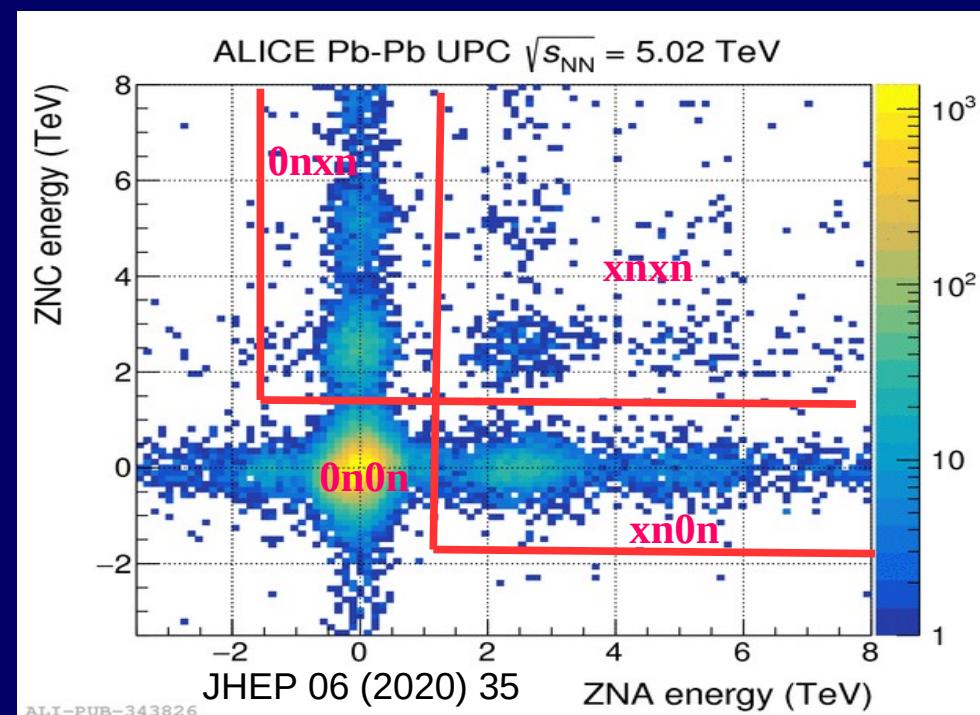

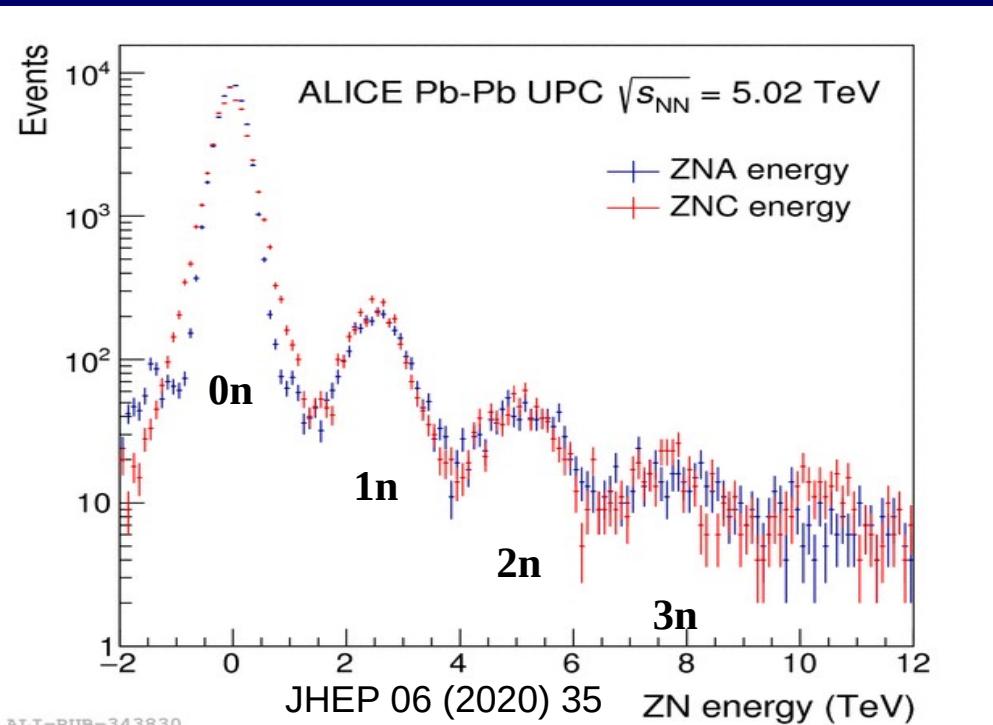

$\gamma+p \rightarrow \text{VM}+p$ cross section + the optical theorem + a Glauber-like eikonal formalism.

Calculations based on **colour-dipole** approach and on **Gribov-Glauber shadowing** approach provide good agreement with the data.

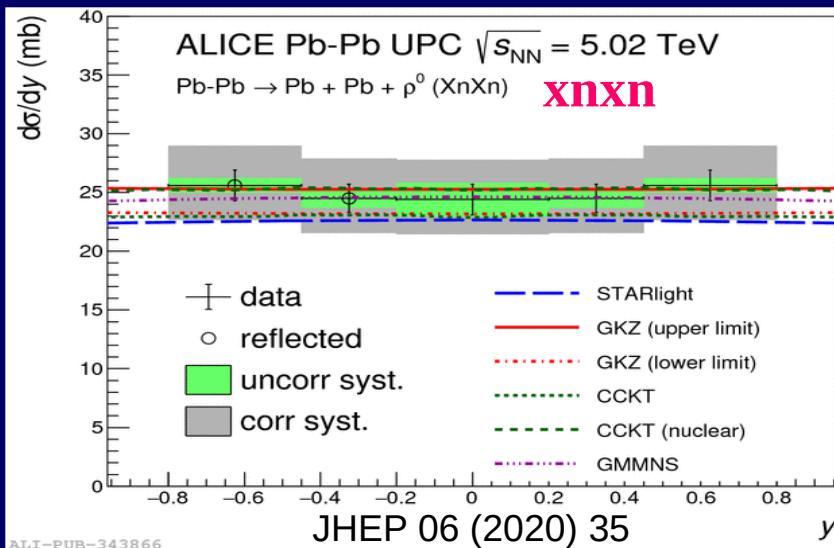

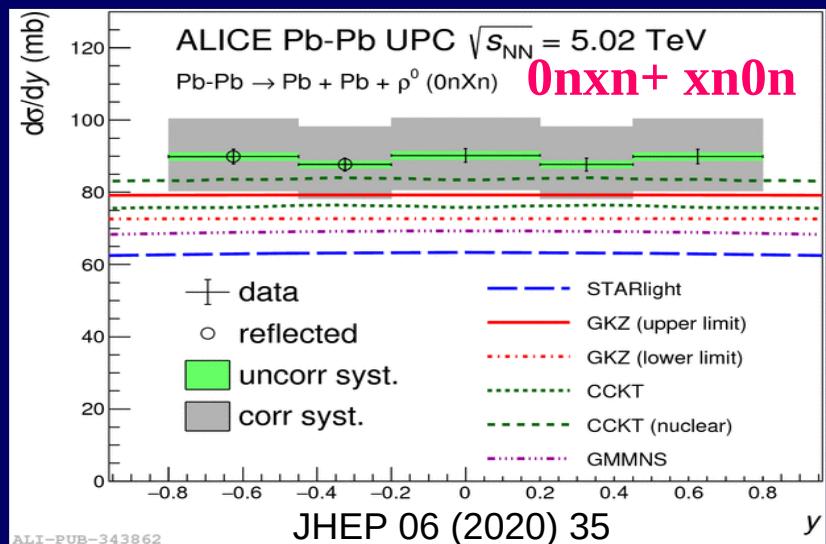

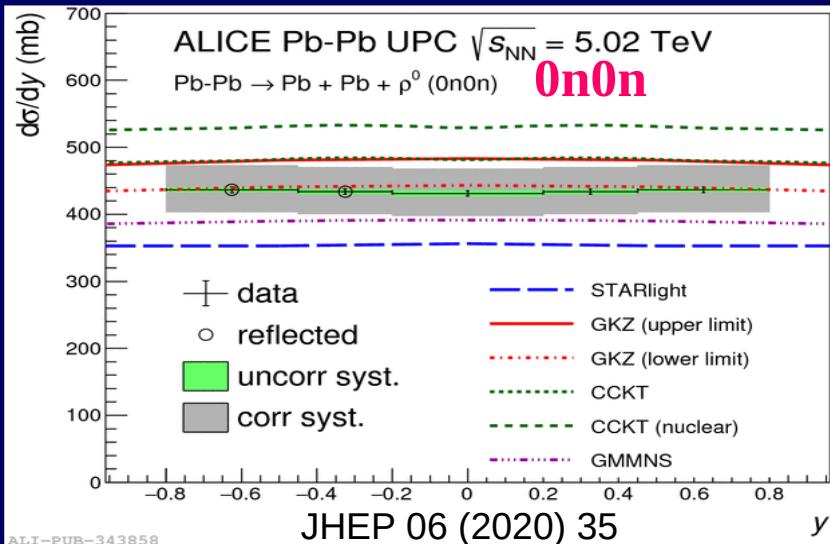

Coherent ρ^0 production in Pb–Pb UPC at $\sqrt{s_{\text{NN}}} = 5.02 \text{ TeV}$ (cont'd)

ALICE is equipped with two ZDC detectors (ZNA and ZNC)

- located at either side of interaction point at $\pm 112.5 \text{ m}$ along the z-axis;
- intended for measurement of neutrons at beam rapidity;
- which provide time resolution enough to separate beam-beam and beam-gas interactions;
- which have a good efficiency to detect neutrons coming from electromagnetic dissociation (EMD) with $|\eta| > 8.8$;
- which have a relative energy resolution of around 20% for a neutron which allows to separate events with either zero or a few neutrons at beam rapidities.

Coherent ρ^0 production in Pb–Pb UPC at $\sqrt{s_{NN}} = 5.02$ TeV (cont'd)

agreement both with models based on colour-dipole approach and with Gribov-Glauber shadowing.

The models for EMD accompanying VM photoproduction describe the measured cross sections for different neutron emission classes which are sensitive to different impact parameter ranges.
