

Analysis of $1/N_c$ corrections in the quark model using the example of the pion transient form factor

Wednesday 1 November 2023 16:10 (15 minutes)

Transitional pion form factor; $1/N_c$ corrections; nonlocal quark model

The fundamental theory of strong interactions is quantum chromodynamics. In the low-energy area, the strong coupling constant is not a small parameter, so the use of methods that do not use perturbation theory, for example, effective quark models, is required.

One of such models is the nonlocal quark model [1]. The model is based on expansion in terms of the inverse number of quarks ($1/N_c$). When considering the diagram technique within the framework of the model, it turns out that any meson propagator in the diagrams leads to a suppression coefficient of $1/N_c$ [2].

A large number of diagrams with $1/N_c$ corrections leads to the need to automate the calculation process. The following calculation program is currently implemented:

- The initial stage of generating diagrams is carried out in the QGRAF program [3]
 - A program was written for processing data generated by QGRAF, where an algorithm for selecting diagrams by $1/N_c$ -indices was implemented
 - Classification of diagrams into certain types has been made
 - Subsequently, the expressions are transferred to the FORM analytical calculation program
- Using the program, the transition form factor of the pion was considered [4].
