### Introduction

- Searching for New Physics in proton-proton collisions at very high energies at the LHC is of a great interest.
- Possible indicator of the New Physics is a muon anomolous magnetic moment.
- The possible New Physics might manifest itself more significantly in muons interactions with large invariant mass.
- The effects coming from Z boson correction to the leading process of the pp scattering via γγ fusion will be investigated.
- The results are contained in the following paper: "Weak interaction corrections to muon pair production via the photon fusion at the LHC Phys. Rev. D 108, 093006 (2023). arXiv:2308.01169

### Results for semi-exclusive e/m muon pair production

Quasielastic case:

$$\sigma_{\sf fid}(pp 
ightarrow p\mu^+\mu^-p) = 8.6 \; {\sf fb}.$$

Inelastic case:

$$\sigma_{\sf fid}(pp 
ightarrow p\mu^+\mu^- X) = 9.2$$
 fb.

Total cross-section is

$$ilde{\sigma}_{\mu\mu+
ho}^{
m fid.} = 18\pm 2$$
 fb.

"pp scattering at the LHC with the lepton pair production and one proton tagging". Eur. Phys. J. C 82, 1055 (2022).
ATLAS results:

 $\sigma^{
m exp.}_{\mu\mu+
m p}=7.2\pm1.6~{
m (stat.)}\pm0.9~{
m (syst.)}\pm0.2~{
m (lumi.)}~{
m fb}.$ 

Phys. Rev. Lett. 125, 261801 (2020).

Taking into account survival factor S(b) leads to agreement with the experimental data at the level of 2 – 3 standard derivations.

### Feynman diagrams for Z contribution

- ▶ Proton survives  $\rightarrow$  upper bound on Z virtuality  $Q^2 \rightarrow$ 
  - ightarrow Z impact suppressed as  $\hat{Q}^2/M_Z^2 \sim 10^{-5}.$
- ▶ Proton disintegrates → perform calculation within the parton model:

$$\sigma(pp 
ightarrow p\mu^+\mu^- X) = \sum_{q} \sigma(pq 
ightarrow p\mu^+\mu^- q).$$

Two types of terms: 1) the interference between γγ and γZ; 2) pure γZ.

### Master formula for $pq \rightarrow p\mu^+\mu^-q$

▶ The cross-section for the reaction  $pq \rightarrow p\mu\mu q$  is:

$$d\sigma_{pq \to p\mu^{+}\mu^{-}q} = \frac{Q_{q}^{2}(4\pi\alpha)^{2}}{q_{1}^{2}q_{2}^{2}}\rho_{\mu\nu}^{(1)}\rho_{\alpha\beta}^{(2)}M_{\mu\alpha}M_{\nu\beta}^{*} \times \\ \times \frac{(2\pi)^{4}\delta^{(4)}(q_{1}+q_{2}-k_{1}-k_{2})d\Gamma}{4\sqrt{(p_{1}p_{2})^{2}-m_{p}^{4}}} \times \\ \times \frac{d^{3}p_{1}^{'}}{(2\pi)^{3}2E_{1}^{'}}\frac{d^{3}p_{2}^{'}}{(2\pi)^{3}2E_{2}^{'}} \times f_{q}(x,Q_{2}^{2})dx,$$

where  $Q_q$  is a quark charge,  $\rho_{\mu\nu}^i$  is a vector boson density matrix,  $M_{\mu\alpha}$  is the amplitude of  $\gamma\gamma/\gamma Z \rightarrow \mu\mu$  process, x is a fraction of the proton momentum carried by quark q and  $f_q(x, Q_2^2)$  is a parton distribution function (PDF). It is convenient to work in helicity representation:

$$ho_1^{\mu\nu} 
ho_2^{lpha\beta} M_{\mu\alpha} M_{\nu\beta}^* = (-1)^{a+b+c+d} 
ho_1^{ab} 
ho_2^{cd} M_{ac} M_{bd}^*.$$
  
where  $a, b, c, d \in \{\pm 1, 0\}.$ 

### Photon density matrices

Photon density matrix can be written as:

$$\rho_{++}^{(1)} = \rho_{--}^{(1)} \approx D(Q_1^2) \frac{2E^2 q_{1\perp}^2}{\omega_1^2 Q_1^2},$$

for the  $\ensuremath{\textit{pp}\gamma}$  vertex and

$$\rho_{++}^{(2)} = \rho_{--}^{(2)} \approx \frac{2x^2 E^2 q_{2\perp}^2}{\omega_2^2 Q_2^2}, \quad \rho_{00}^{(2)} \approx \frac{4x^2 E^2 q_{2\perp}^2}{\omega_2^2 Q_2^2},$$

for the  $qq\gamma$  vertex. Here  $q_{i\perp}^2 \approx Q_i^2 - \omega_i^2/\gamma^2$  and  $D(Q_1^2)$  is a combination of Sachs form factors of the proton:

$$D(Q_1^2) = \frac{G_E^2(Q_1^2) + (Q_1^2/4m_p^2)G_M^2(Q_1^2)}{1 + Q_1^2/4m_p^2}$$

### Z boson density matrices

Z interaction with quarks looks like:

$$\Delta L_{qqZ} = \frac{e}{s_W c_W} \left[ \frac{g_V^q}{2} \bar{q} \gamma_\alpha q + \frac{g_A^q}{2} \bar{q} \gamma_\alpha \gamma_5 q \right] Z_\alpha, \quad s_W \equiv \sin \theta_W,$$
(1)

$$c_W \equiv \cos heta_W, \quad g_V^q = T_3^q - 2Q_q s_W^2, \quad g_A^q = T_3^q.$$

• Under approximation  $\omega_2/xE \ll 1$  one obtains for the interference density matrix:

$$\tilde{\rho}_{ab}^{(2)} \approx \frac{g_V^q}{2} \rho_{ab}^{(2)},$$

and for the Z only:

$$ilde{
ho}^{(2)}_{ab} pprox rac{\left(g^{q}_{V}
ight)^{2} + \left(g^{q}_{A}
ight)^{2}}{4}
ho^{(2)}_{ab},$$

where  $\rho_{ab}^{(2)}$  is a photon density matrix in the helicity representation.

## Z contribution into the amplitude $M_{\gamma\gamma+\gamma Z}$

- The following statements can be proved:
  - 1. Interference between the processes due to vector and axial-vector interaction is identically zero.
  - 2. The square of the amplitude with the axial coupling equals that with the vector coupling (under approximation  $W \gg m_{\mu}$ , W is muon pair invariant mass).
- This leads us to a simple factorization of the correction due to weak interaction in the total amplitude:

$$|M_{\gamma\gamma+\gamma Z}|^2 \equiv \varkappa |M_{\gamma\gamma}|^2,$$

where

$$\begin{split} \varkappa(Q_2^2) &= 1 + 2\frac{g_V^{\mu}}{Q_{\mu}}\frac{g_V^{q}}{Q_{q}}\lambda + \frac{\left(g_A^{q}\right)^2 + \left(g_V^{q}\right)^2}{Q_{\mu}^2}\frac{\left(g_A^{\mu}\right)^2 + \left(g_V^{\mu}\right)^2}{Q_q^2}\lambda^2\\ \text{and } \lambda &= \frac{1}{\left(2s_W c_W\right)^2 \left(1 + M_Z^2/Q_2^2\right)}. \end{split}$$

### Helicity amplitudes

The following expressions for the diferent polarizations can be obtained:

$$|M_{+0}|^{2} + |M_{-0}|^{2} = (4\pi\alpha)^{2} \frac{32Q_{2}^{2}}{W^{2}(1+Q_{2}^{2}/W^{2})^{2}} \varkappa.$$

When  $Q_2^2 = 0$  the square  $|M_{\pm 0}|^2 = 0$ .

$$|M_{+-}|^{2} + |M_{-+}|^{2} = (4\pi\alpha)^{2} \frac{4\sin^{2}\theta(1+\cos^{2}\theta)}{(1+Q_{2}^{2}/W^{2})^{2}} \times \left[\frac{1}{1-v\cos\theta} + \frac{1}{1+v\cos\theta}\right]^{2}\varkappa,$$

where  $v = \sqrt{1 - 4m_{\mu}^2/W^2}$ . For  $\theta = 0, \pi$  the  $|M_{\pm\mp}|^2 = 0$  due to the helicity conservation.

### Chiral anomaly

For the ++ polarizations (and -- in the same way) one can write:

$$|M_{++}|^2 \sim [...] \sin^2 \theta + \left\{ \frac{1 - v^2}{(1 + v \cos \theta)^2} + \frac{1 - v^2}{(1 - v \cos \theta)^2} \right\}.$$

In the limit m<sub>μ</sub> ≪ W the term [...] sin<sup>2</sup> θ = 0 when θ = 0, π but the term in curly braces {...} ≠ 0 and gives finite contribution into the cross section. It is the manifestation of the chiral anomaly.

### Master formula for $pp \rightarrow p\mu\mu X$ with Z correction

Substituting density matrices and amplitude into the master formula and summing over all valent and sea quarks q one obtains:

$$\begin{split} \frac{\mathrm{d}\sigma_{pp\to p\mu^+\mu^- X}}{\mathrm{d}W} = & \frac{4\alpha W}{\pi} \sum_{q} Q_q^2 \int_{\frac{W^4}{36\gamma^2 s}}^{s} \frac{\sigma_{\gamma\gamma^* \to \mu^+\mu^-}(W^2, Q_2^2)}{(W^2 + Q_2^2)Q_2^4} \cdot \varkappa \left(Q_2^2\right) \cdot \mathrm{d}Q_2^2 \times \\ & \times \int_{\frac{W^2 + Q_2^2}{s} \cdot \max}^{1} \mathrm{d}x f_q(x, Q_2^2) \int_{\frac{1}{2}\ln\left(\frac{W^2 + Q_2^2}{x^{2s}} \cdot \max\left(1, \frac{m_p}{9Q_2^2}\right)\right)} \\ & \frac{W^2 + Q_2^2}{s} \cdot \max\left(1, \frac{m_p}{s\sqrt{Q_2^2}}\right) \frac{1}{2}\ln\left(\frac{W^2 + Q_2^2}{x^{2s}} \cdot \max\left(1, \frac{m_p^2}{9Q_2^2}\right)\right) \end{split}$$

where y is a rapidity of a muon pair  $y = (1/2) \ln \omega_1 / \omega_2$ ,  $\gamma = E/m$  and  $n_p(\omega_1)$  is a modified equivalent photon spectrum of a proton:

$$n_p(\omega_1) = \frac{\alpha}{\pi\omega_1} \int_0^\infty \frac{D(Q_1^2) q_{1\perp}^2 \mathrm{d} q_{1\perp}^2}{Q_1^4}.$$

▶ If the lower limit on  $p_T^{\mu\mu}$  grows the correction becomes larger:

### Conclusion

- The contribution of Z boson into the semi-exclusive muon pair production in the ultrarelativistic proton-proton collisions at the LHC was investigated.
- Analytical formulas describing weak interaction correction into the cross section of  $pp \rightarrow p\mu\mu X$  process were obtained.
- lt was shown by means of helicity representation for the amplitudes that  $M_{\pm\pm}$  term contains chiral anomaly.
- The numerical integration was performed with help of the special library *libepa*.
- lt was shown that with the larger lower limit on  $p_T^{\mu\mu}$  the contribution goes up to 20%.
