

Performance of the Scintillation Wall in the BM@N experiment

Volkov Vadim
on behalf of INR RAS group

The 28th International Scientific Conference of Young Scientists and Specialists (AYSS-2024)
30 October 2024

Scintillation Wall for fragments charge measurements and reaction plane estimation

- 36 small inner cells 7.5×7.5×1 cm³ + 138 big outer cells 15×15×1 cm³
- light yield for MIP signal – small cells 55 p.e.±2.4%; big cells 32 p.e.± 6%.
- beam hole
- covered with a light-shielding aluminum plate
- light collection by WLS fibers
- light readout with SiPM (Hamamatsu MPPC S14160-1310PS) mounted on the PCB at each scint. cell

light collection from tiles

3.8 GeV

- readout divided into 12 sectors each one equipped with single temperature sensor
- each 4 sectors are read by combined electronics unit:
 - One ADC64s2 board
 - Four 16-channels FEE boards
 - Voltage control unit

Spectra of charges for small scintillator detectors after calibration

The fragments with $Z = 3$ and beyond mainly pass through the beam hole and are not detected by the most of the scintillator detectors.

Spectra of charges for large scintillator detectors after calibration

In the large outer scintillation detectors only the $Z = 1$ peak being clearly visible.

Data for run8.

ScWall stability during the run8

Data for **Xe+CsI** are presented for all data on a file-by-file basis for energies of 3.0 and 3.8 GeV for ScWall

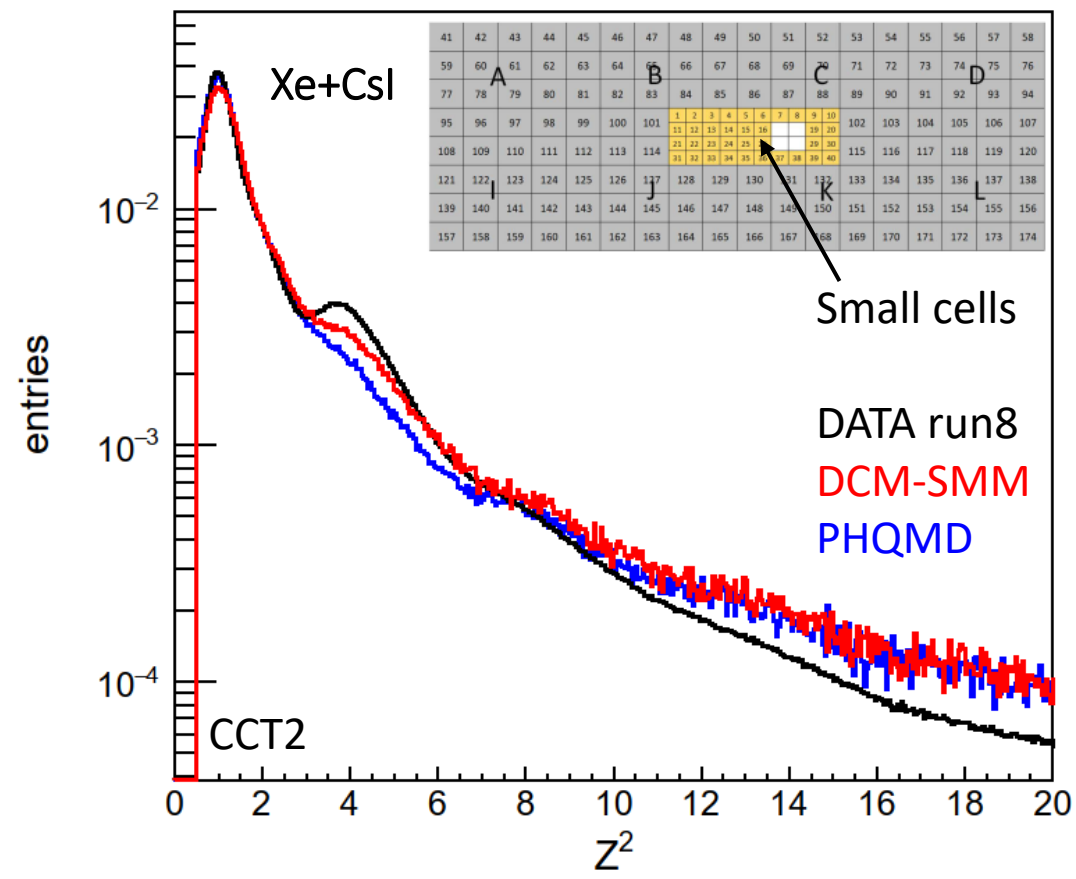

+ -5σ dashed lines are shown

The mean total charge values for ScWall for each file are presented.

Applied cuts: Single Xe, vertex Z ($-1.5 \text{ cm} < Z < 1.5 \text{ cm}$), ≥ 2 tracks in vertex reconstruction

Charges spectra

The charge spectrum on the ScWall is in the range up to $Z = 2$ (small cells).

Large charges leak out into the hole.

In the cells around the hole, charges up to $Z = 4$ can be detected.

The shift of the peaks is due to the Birks effect.

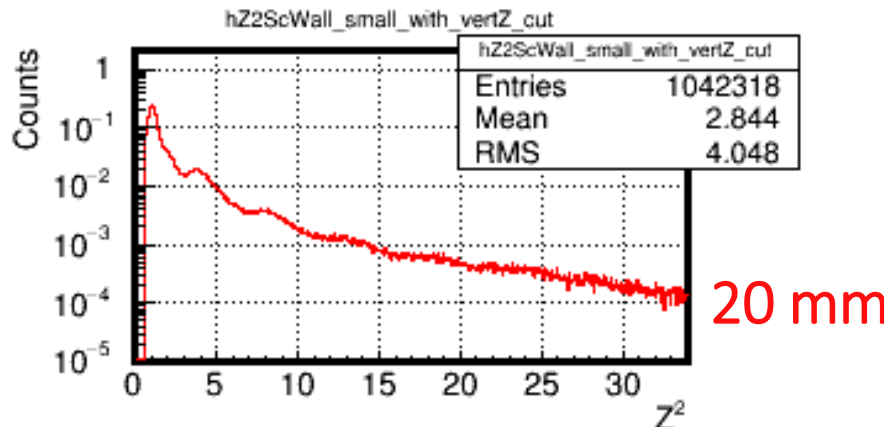

The charge yields in the experiment and in the simulation data for $Z = 2$ are significantly different.

Particle yield difference in the models and data is related to the angular distribution of the particles.

Future upgrade of ScWall

Simulation

ScWall Z² distributions XeCs@3.26AGeV
DCM-QGSM-SMM

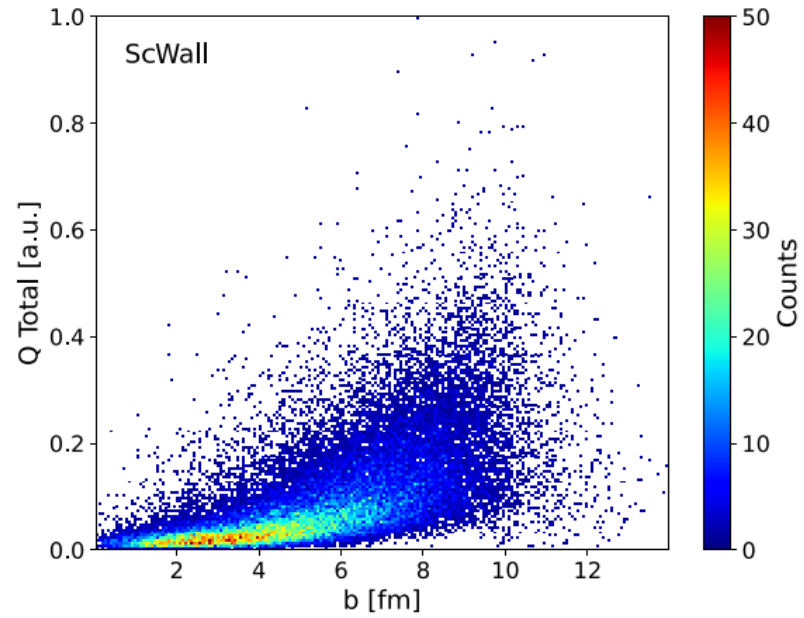

Cosmic tests

Research on the cosmic shows two times greater amplitude for 2x10 mm cells.

The **range** of charges detected on the ScWall is much **greater** (up to Z = 5) in small cells when **thicker** cells (20 mm) are used according to the DCM-QGSM-SMM simulation.

Centrality estimators

(a)

(b)

As an estimator of centrality, FHCAL E_{dep} performs best (b) (similar to the number of tracks).

The scintillation wall (a) can sense centrality, but much worse.

It is possible to use the combined observable of these quantities to determine centrality.

DCM—SMM 3.8 GeV

Centrality estimators and combination of observables

The combined usage of the energy deposition in the FHCAL and the total charge on the ScWall gives a narrower distribution.

The centrality accuracy improves only within 1%.

Need to consider autocorrelations with FHCAL.

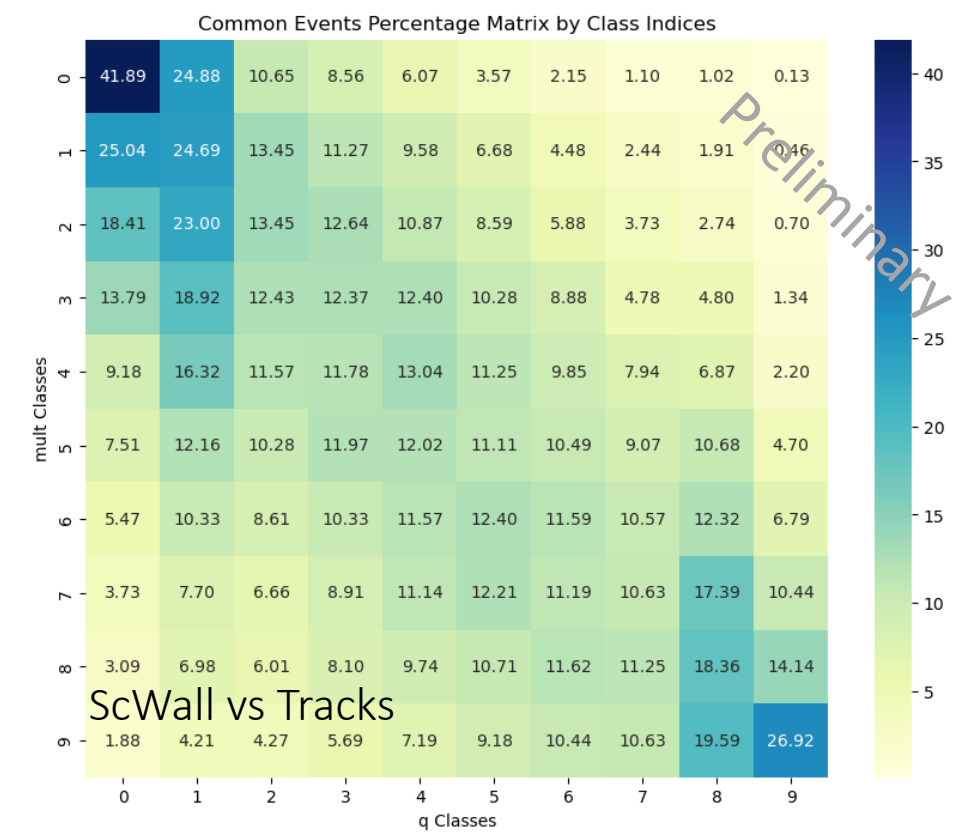

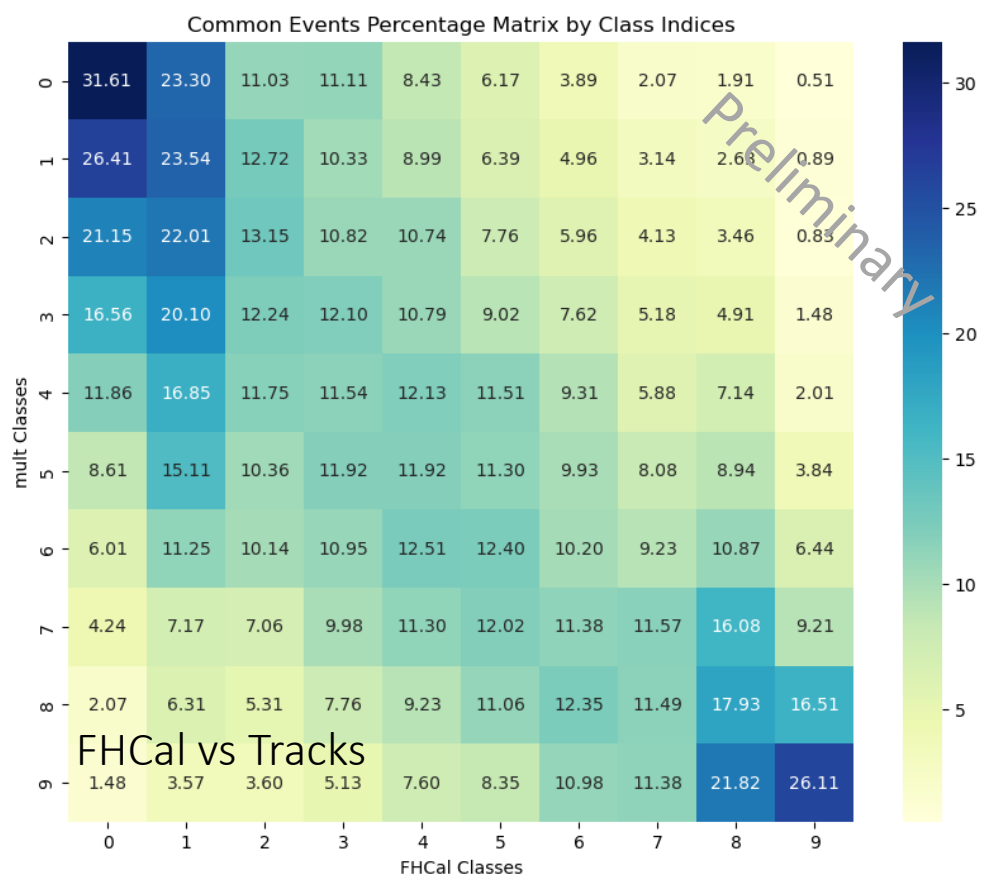

Centrality estimators: ScWall vs FHCaI

The width of the distributions of the presented observables as a dependence of the impact factor shows that the ScWall is significantly inferior to the FHCaI.

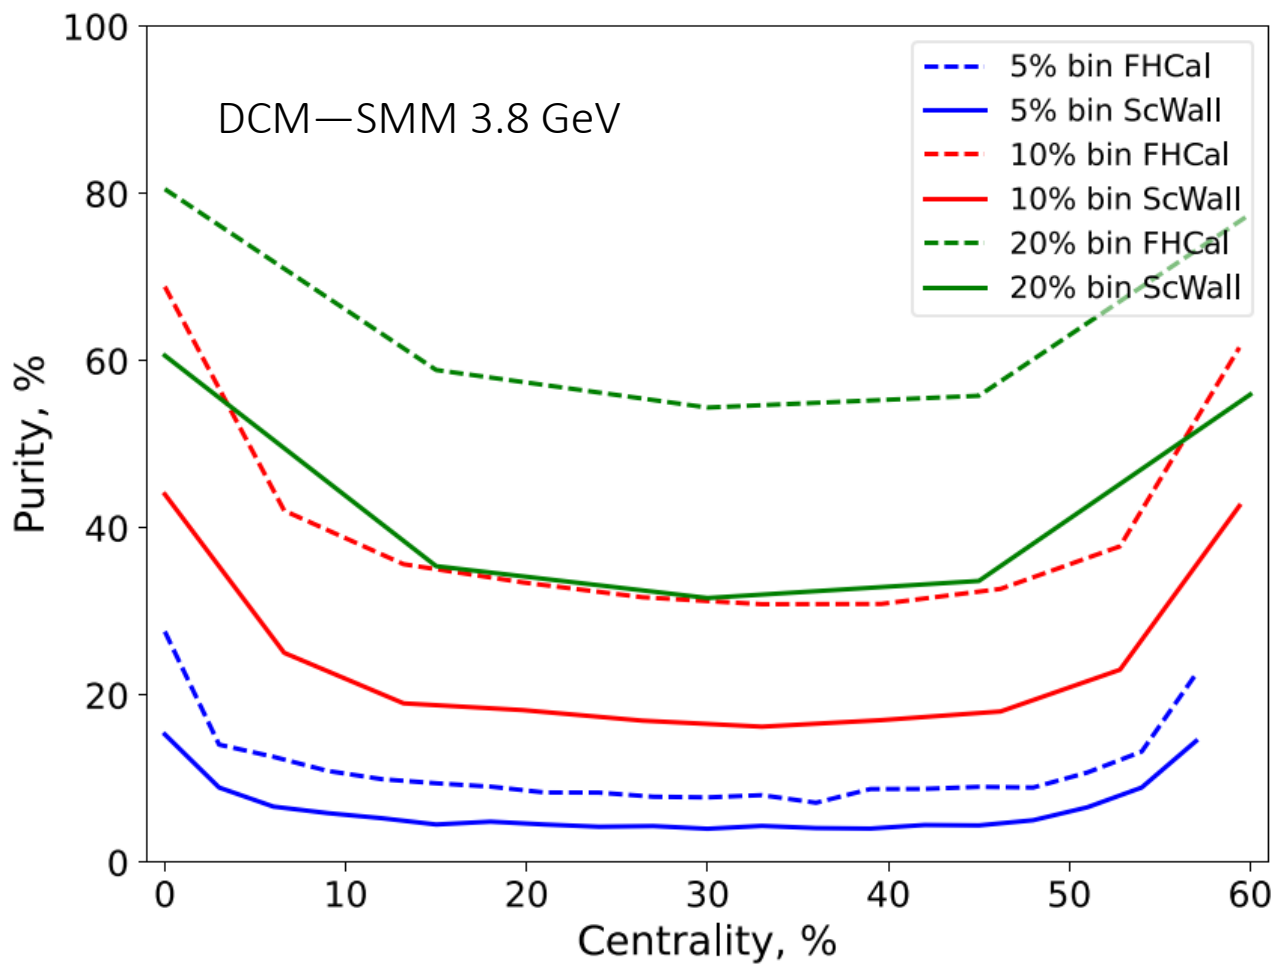

The difference for the most central events in standard deviation units is about 2 times.

Centrality estimators: mixing

- How many of the same events are in the same centrality class determined from different observables.
- The number of total events for ScWall and Tracks for more centrality classes is higher than for FHCAL and Tracks.
- At the same time, this may be a consequence of the wider b distributions for ScWall. Further study is needed.

Purity and centrality for FHCaI and ScWall

To obtain the required purity of 80% for the most central class, it is necessary to take classes size of at least 20%.

Flow measurements theory

The azimuthal angle distribution is decomposed in a Fourier series relative to reaction plane angle:

$$\rho(\varphi - \Psi_{RP}) = \frac{1}{2\pi} \left(1 + 2 \sum_{n=1}^{\infty} v_n \cos n(\varphi - \Psi_{RP}) \right)$$

Anisotropic flow: $v_n = \langle \cos [n(\varphi - \Psi_{RP})] \rangle$

Reaction plane is not experimentally measured, we define the symmetry plane (SP) from spectators:

$$Q_1 = \sum_{k=1}^N w_k (\cos \phi_k, \sin \phi_k) = |Q_1| (\cos \Psi_{SP}, \sin \Psi_{SP})$$

Directed flow is measured

$$v_1 = \frac{\langle \cos(\phi - \Psi_{SP}) \rangle}{R_1}$$

Resolution correction factor

$$R_1 = \langle \cos(\Psi_{SP} - \Psi_{RP}) \rangle$$

Comparison of RP resolution from FHCAL and ScWall

Scalar product (SP) method:

$$v_1 = \frac{\langle u_1 Q_1^{F1} \rangle}{R_1^{F1}} \quad v_2 = \frac{\langle u_2 Q_1^{F1} Q_1^{F3} \rangle}{R_1^{F1} R_1^{F3}}$$

Where R_1 is the resolution correction factor

$$R_1^{F1} = \langle \cos(\Psi_1^{F1} - \Psi_1^{RP}) \rangle$$

Symbol "F2(F1,F3)" means R_1 calculated via (3S resolution):

$$R_1^{F2(F1,F3)} = \frac{\sqrt{\langle Q_1^{F2} Q_1^{F1} \rangle \langle Q_1^{F2} Q_1^{F3} \rangle}}{\sqrt{\langle Q_1^{F1} Q_1^{F3} \rangle}}$$

3 vectors (F1, F2, F3 and S1, S2, S3) each from FHCAL and ScWall were selected and the resolutions were compared.

The ScWall symmetry plane is more fluctuating. Hence SP has lower resolution, and requires more statistics for flow calculations.

Conclusion

- The ScWall performance during run8 was demonstrated
 - ScWall was stable during run8
 - Charge spectra up to $Z = 2$, in central small cells up to $Z = 4$
 - Upgrade (20 mm cells) can significantly improve charge separation
- ScWall centrality and RP are compared with FHCAL, Hodoscope and other variables
 - ScWall is weakly correlated with centrality
 - ScWall has worse capability for RP determination
- The ScWall can be used to measure the charged fragment-spectator yields. Such data are important for further constraints on the models.

Thank you for your attention!

backup

Scintillation Wall for fragments charge measurements and reaction plane estimation

- 36 small inner cells $7.5 \times 7.5 \times 1 \text{ cm}^3$ + 138 big outer cells $15 \times 15 \times 1 \text{ cm}^3$
- light yield for MIP signal – small cells 55 p.e. $\pm 2.4\%$; big cells 32 p.e. $\pm 6\%$.
- optional beam hole (covered with 4 small cells for the SRC run)
- covered with a light-shielding aluminum plate
- light collection by WLS fibers
- light readout with SiPM mounted on the PCB at each scint. cell

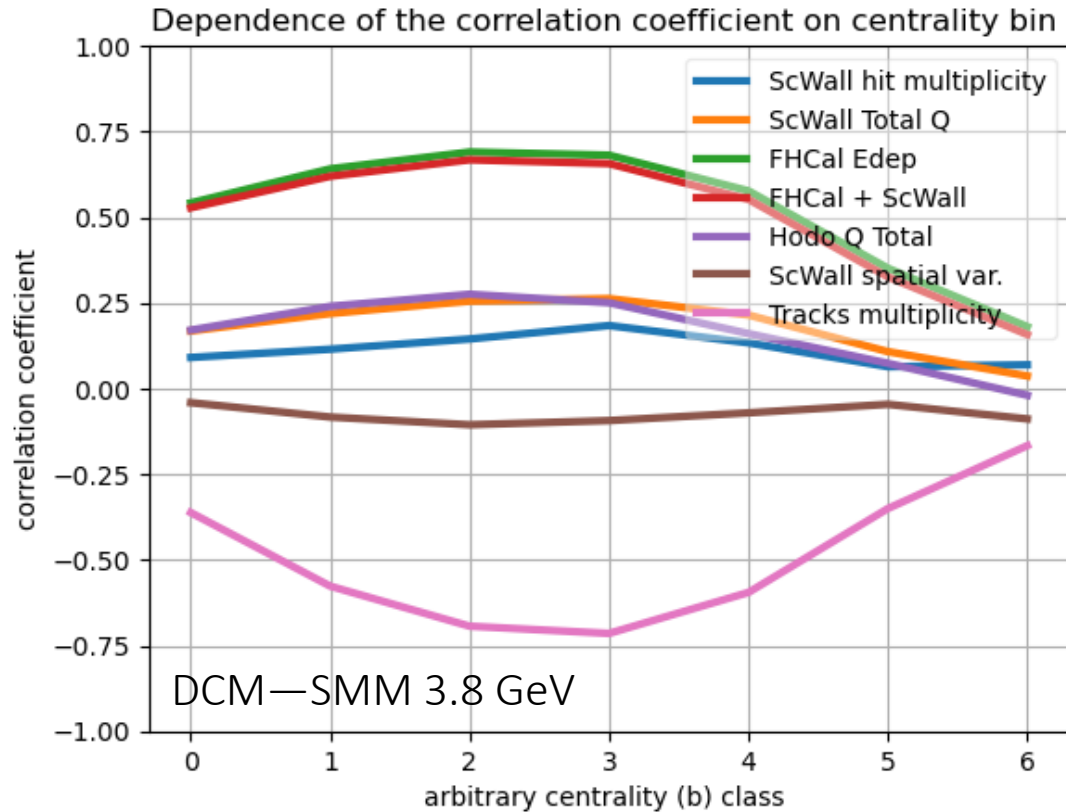

light collection from tiles

- Hamamatsu MPPC S14160-1310PS
- $1.3 \times 1.3 \text{ mm}^2$
- Number of pixels: 2668
- Gain: 7×10^5
- PDE: 25%

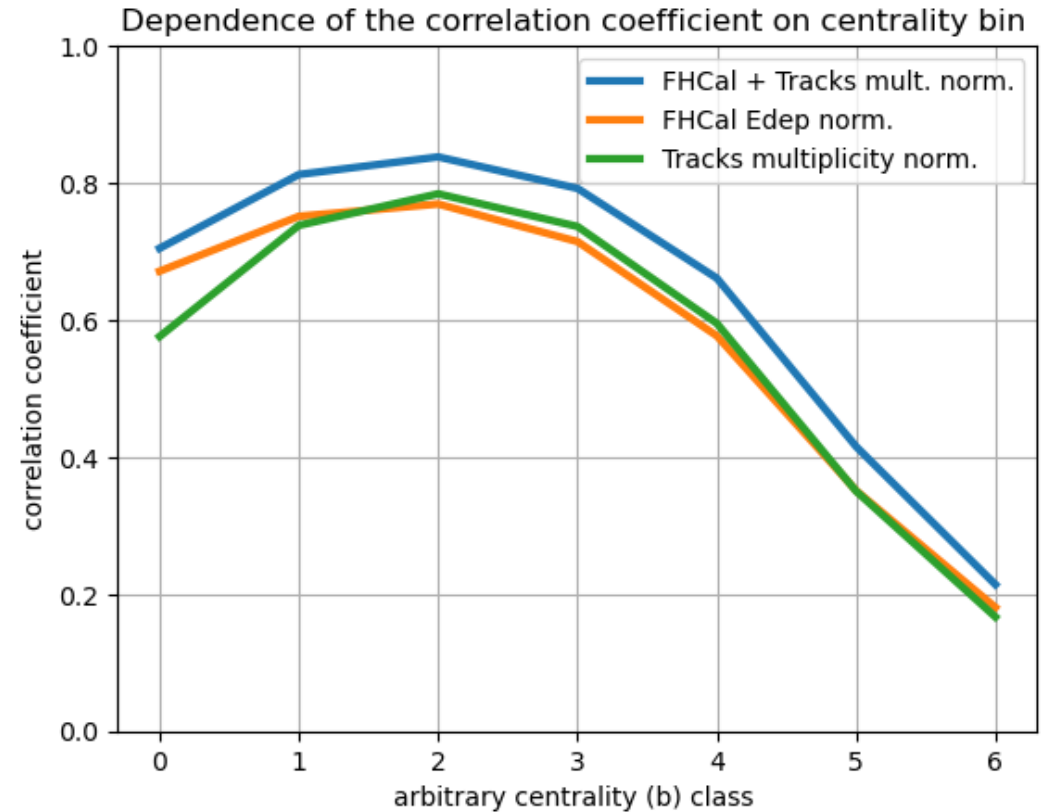

Centrality estimators: correlations

The best observables for centrality are tracks multiplicity and energy deposition in the FHCAL.

The ScWall can only be used to slightly improve the results.

The combined usage of tracks multiplicity energy deposition in the FHCAL can significantly improve the results.

[Pearson](#) correlation coefficient is used.

Common Events Percentage Matrix by Class Indices

Charge distribution in ScWall cells (CCT2)

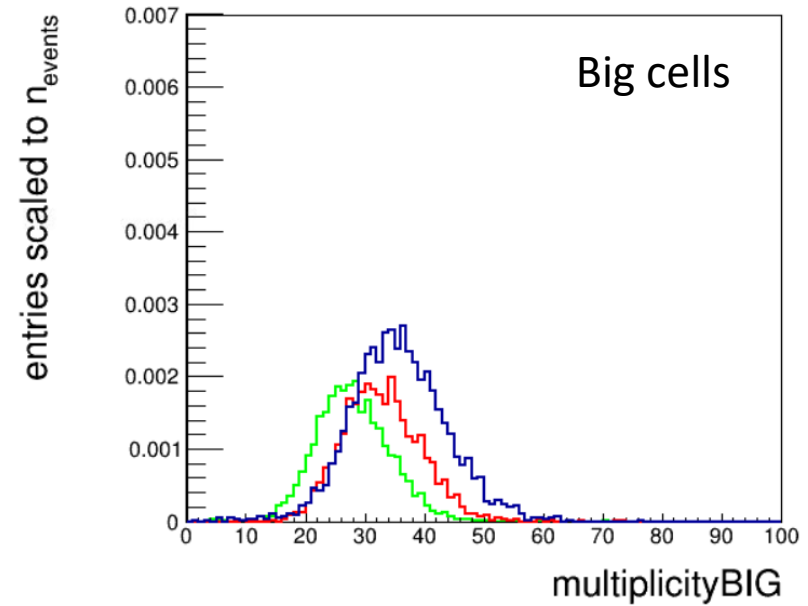

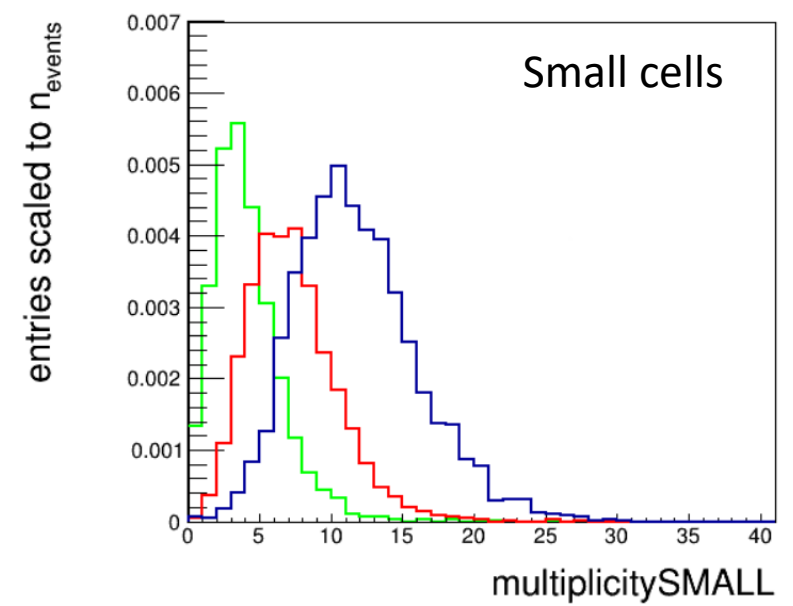

Charge distribution over the scintillation wall. A peaks corresponding to charges $Z = 1, 2$ can be clearly seen.

Charge distribution in ScWall cells

- Comparison of the charge distributions over the scintillation wall for the two energies at 3.0 and 3.8 GeV for the CCT2 trigger.
- The two cell types (small and big) are presented separately.
- It can be seen that the distributions are very similar, with a slight difference in the second peak.

ScWall multiplicity distributions of charged particles for different centrality classes

ScWall multiplicity refers to the number of fired cells in the wall.

Multiplicity is sensitive to centrality -> can be used as estimator. Green, red and blue reflect the most central, semi-central and semi-peripheral arbitrary classes of events.

~50% of minbias events, need to be checked with sim ($b < 10$ fm).

- Cuts:
- BC1S (1 Xe)
 - Z^2 (ScWall) > 0.4
 - vertex Z (-1.5 < Z < 1.5)
 - Z^2 (FQH) < 50

MBT

Multiplicity in ScWall / multiplicity in BD

Multiplicity correlates with energy deposition in the calorimeter, and anticorrelates with multiplicity in BD.

Ambiguity in multiplicity vs number of global tracks

Multiplicity distribution of charged particles in ScWall

Multiplicity is sensitive to charges on the wall for both energies. The peak corresponding to the single charge is clearly prominent.

This dependency can be used for comparison with Monte Carlo models (DCM-QGSM-SMM etc.)
