Decay properties of heavy and super-heavy nuclei

The present work is devoted to the description of quasi-neutron structure of odd isotones in chains with N=149, N=151, N=153. The minimization of potential surface with respect to collective parameters was carried out in order to define ground states and describe low lying quasi-neutron states in the frame of two center shell model. The blocking effect was taken into account as well, transition probabilities and corresponding lifetimes for low lying quasi-neutron states were estimated.
