

# FCalPulse testbeam simulation

Munira Manashova (INP-Kazakhstan & JINR-Dubna)

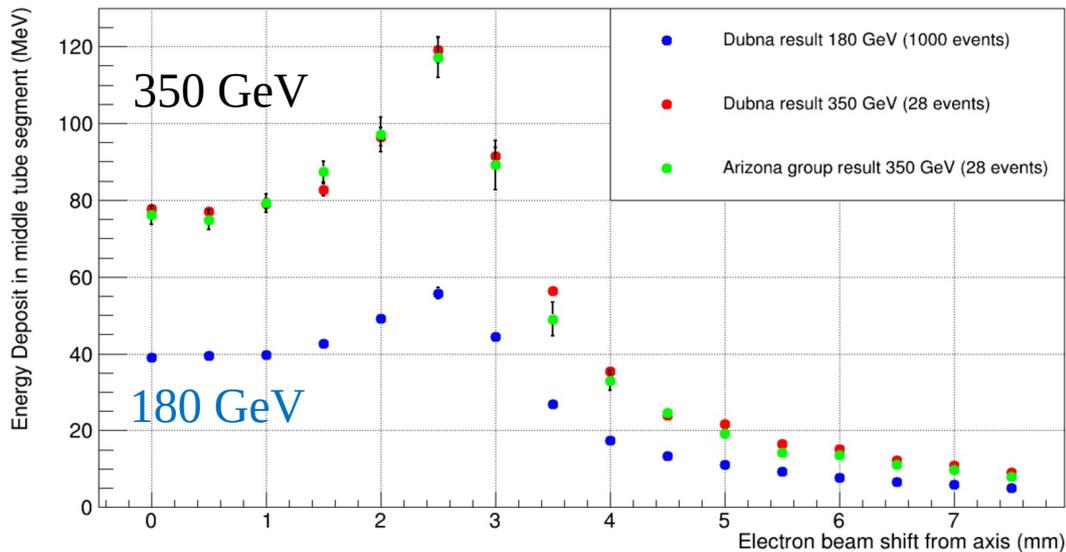

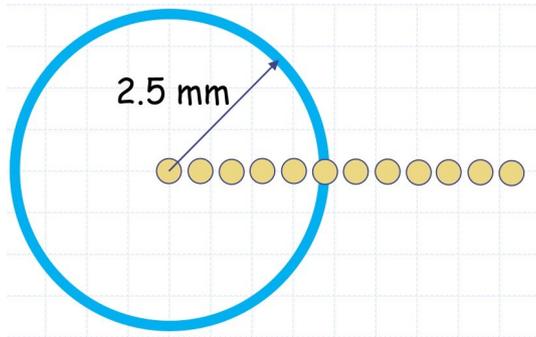

**Outlook: new (corrected) results and homework**

# LAr GEANT4 geometry for 180 GeV test beam

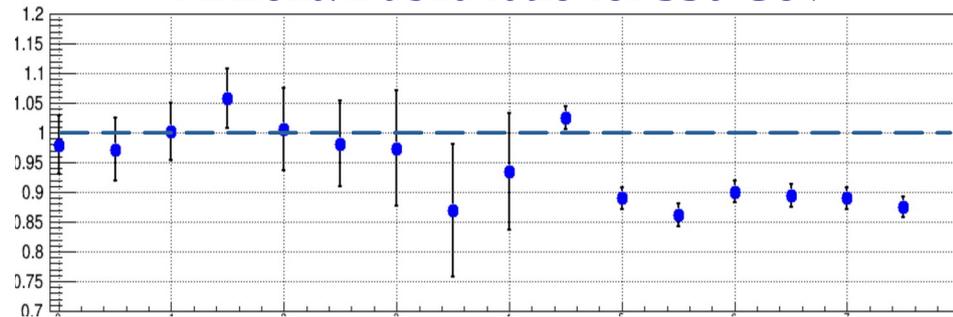

ALL DIMENSIONS ARE IN MILLIMETERS.  
DIMENSIONS ARE FOR SYSTEM AT LIQUID ARGON TEMPERATURE (~88K).  
UPDATED: 2023-04-05

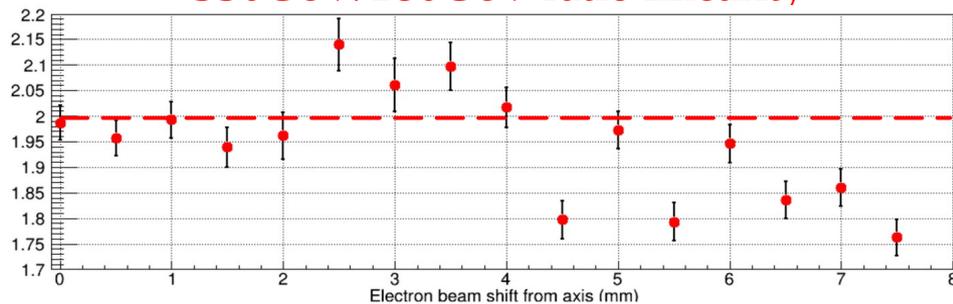

# Reference points

## Arizona/Dubna ratio for 350 GeV

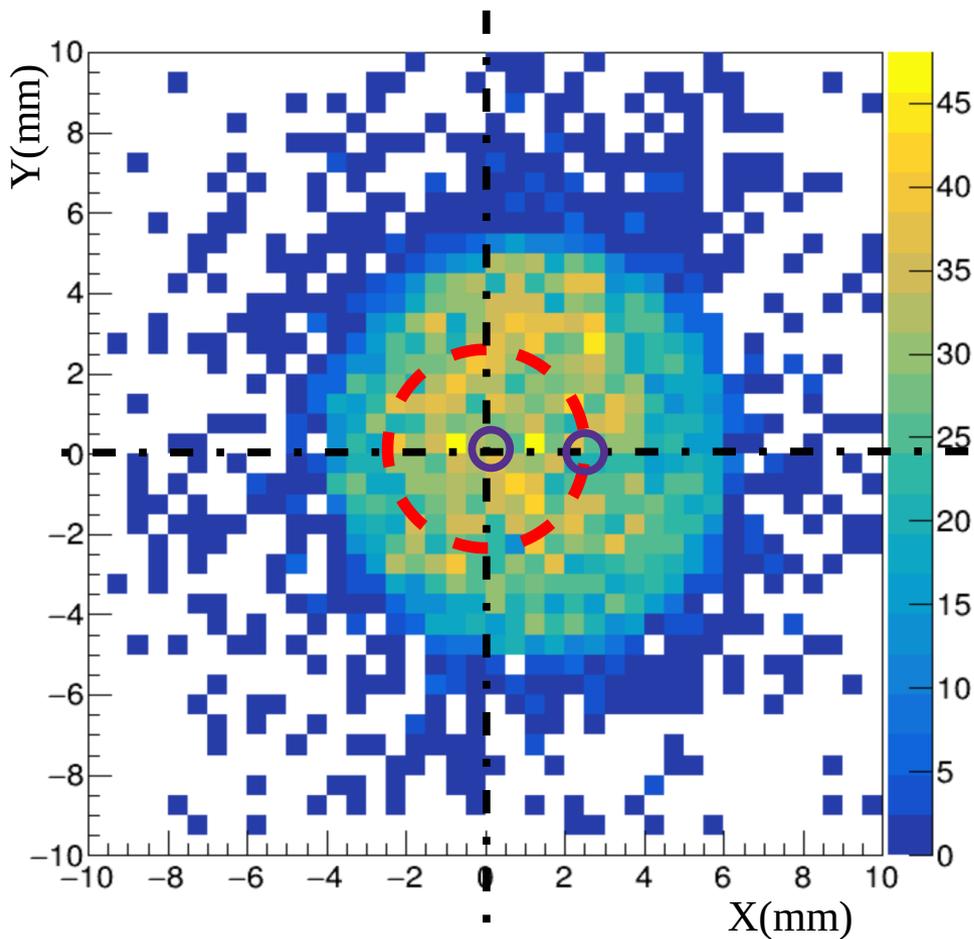

## 350GeV/180GeV ratio linearity

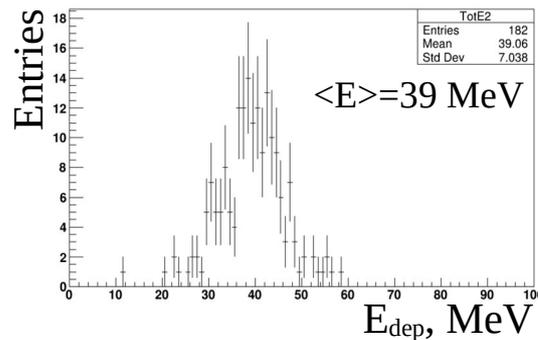

- We reproduced Arizona results for 350 GeV
- 1000 electrons were simulated for 180 GeV
- New results are in agreement with expectations

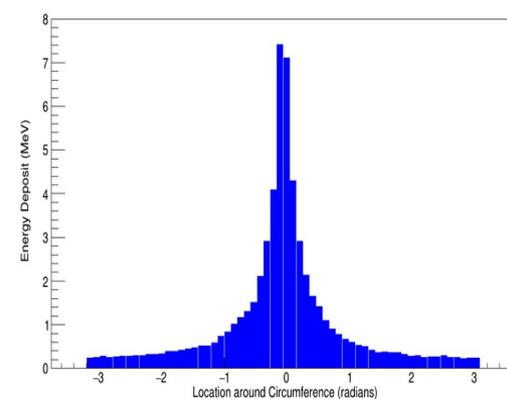

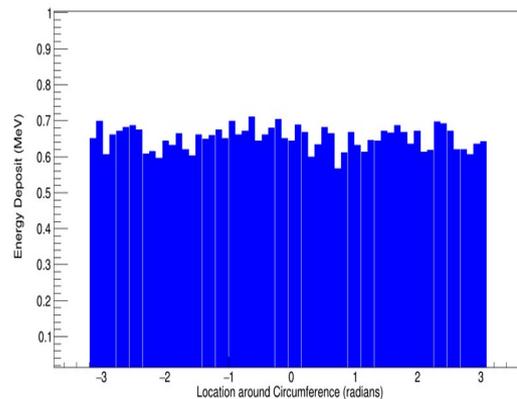

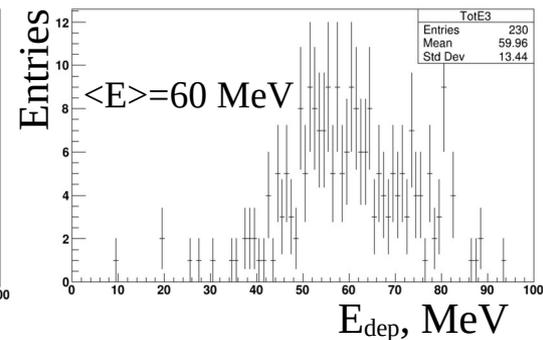

# Deposited energy for two ref. points at $X = 0$ and $X = 2.5$ mm

Offset 0 mm

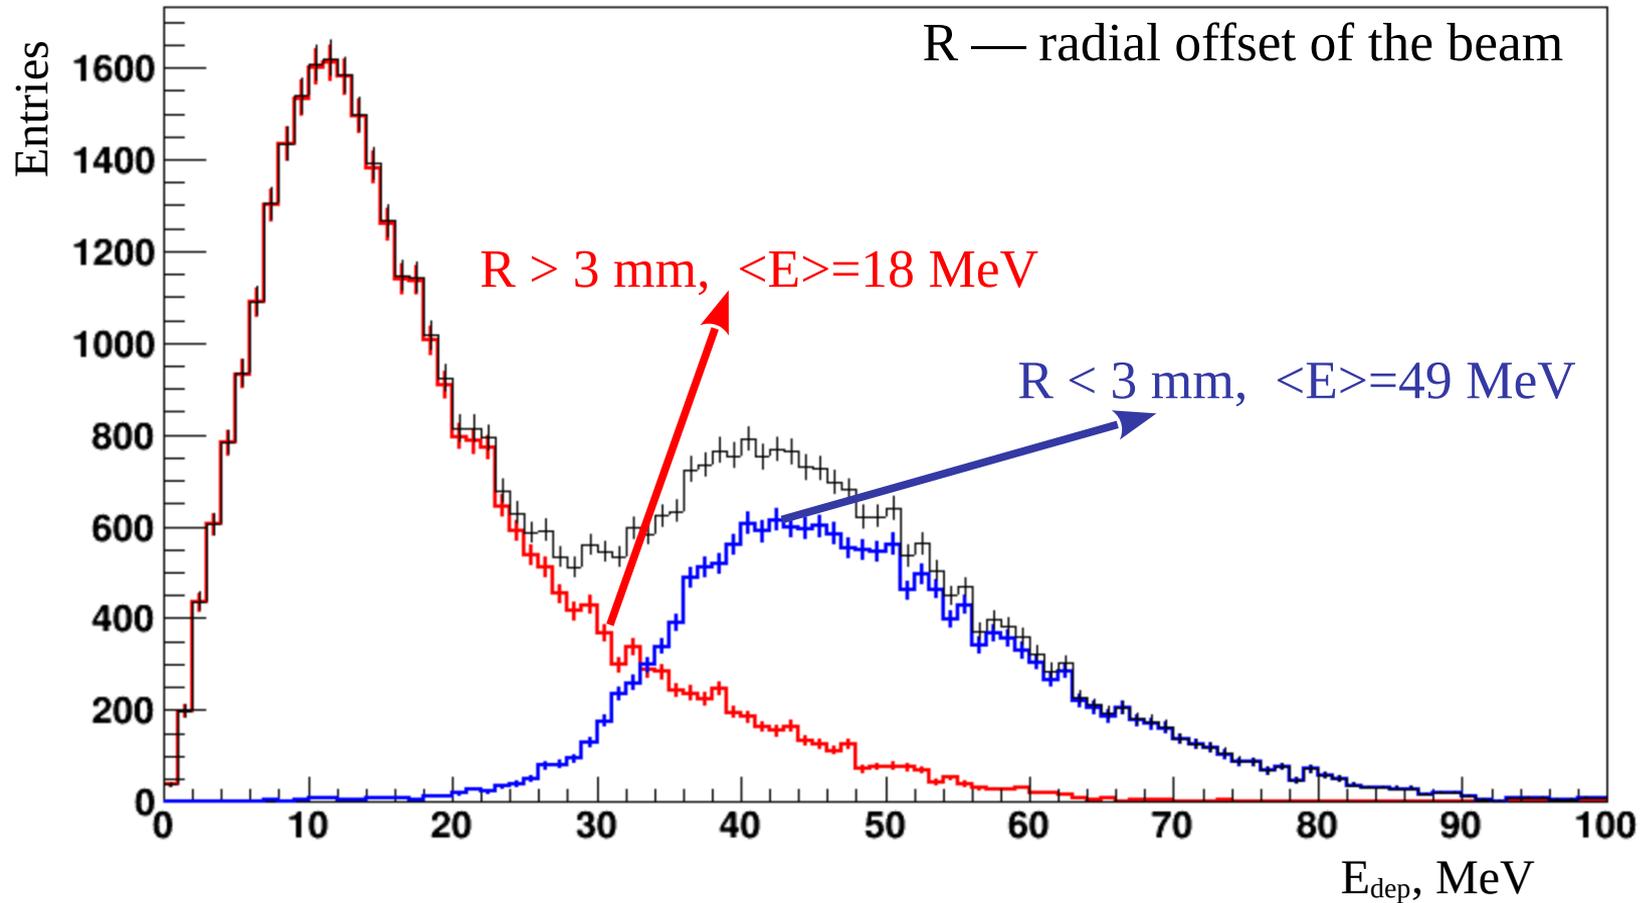

Offset 2.5 mm

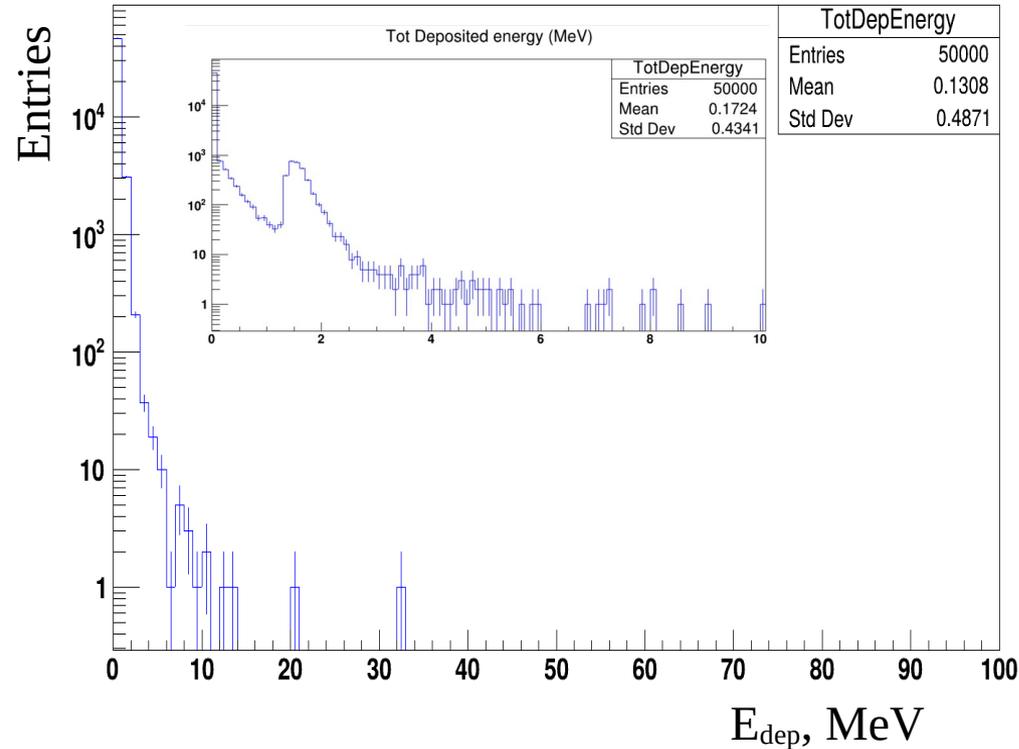

➤ Good agreement with expectations, both for  $E_{dep}$  and  $\phi$ -profile

# Total deposited energy for 180 GeV (no Sr-source)

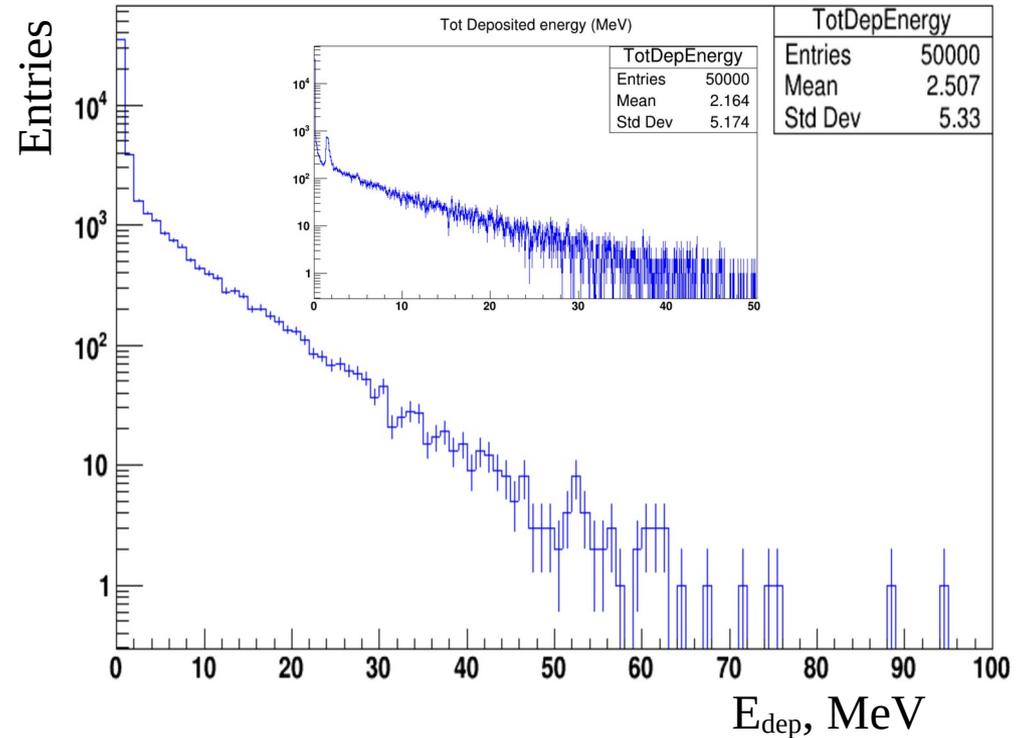

# Total deposited energy for 180 GeV $\mu$ and $\pi$ (no Sr-source)

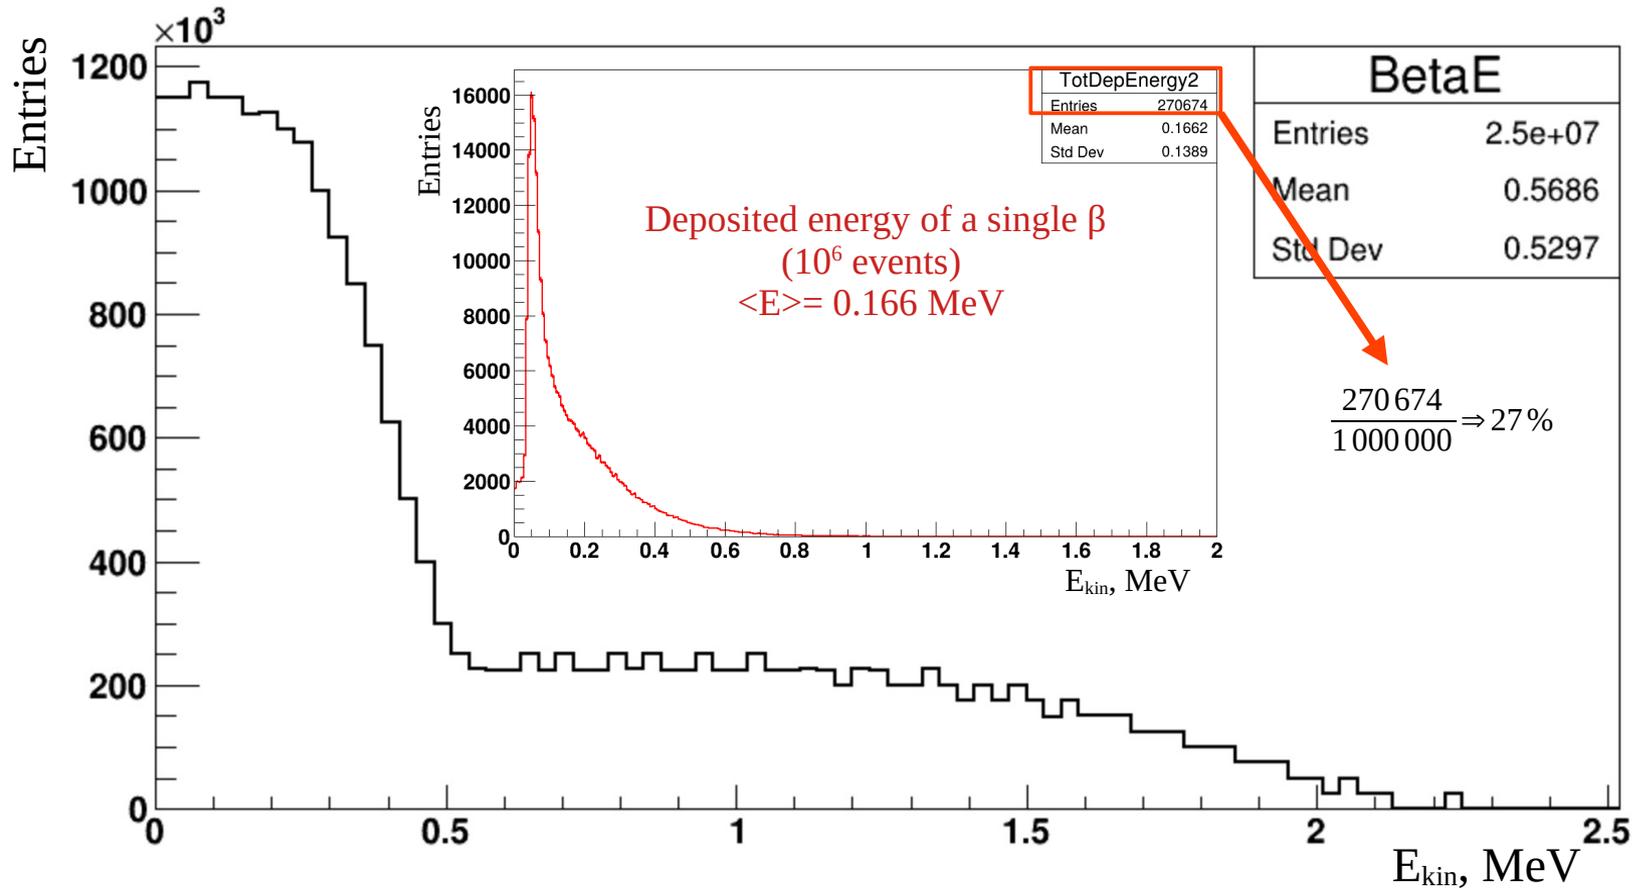

$\mu$ -beam

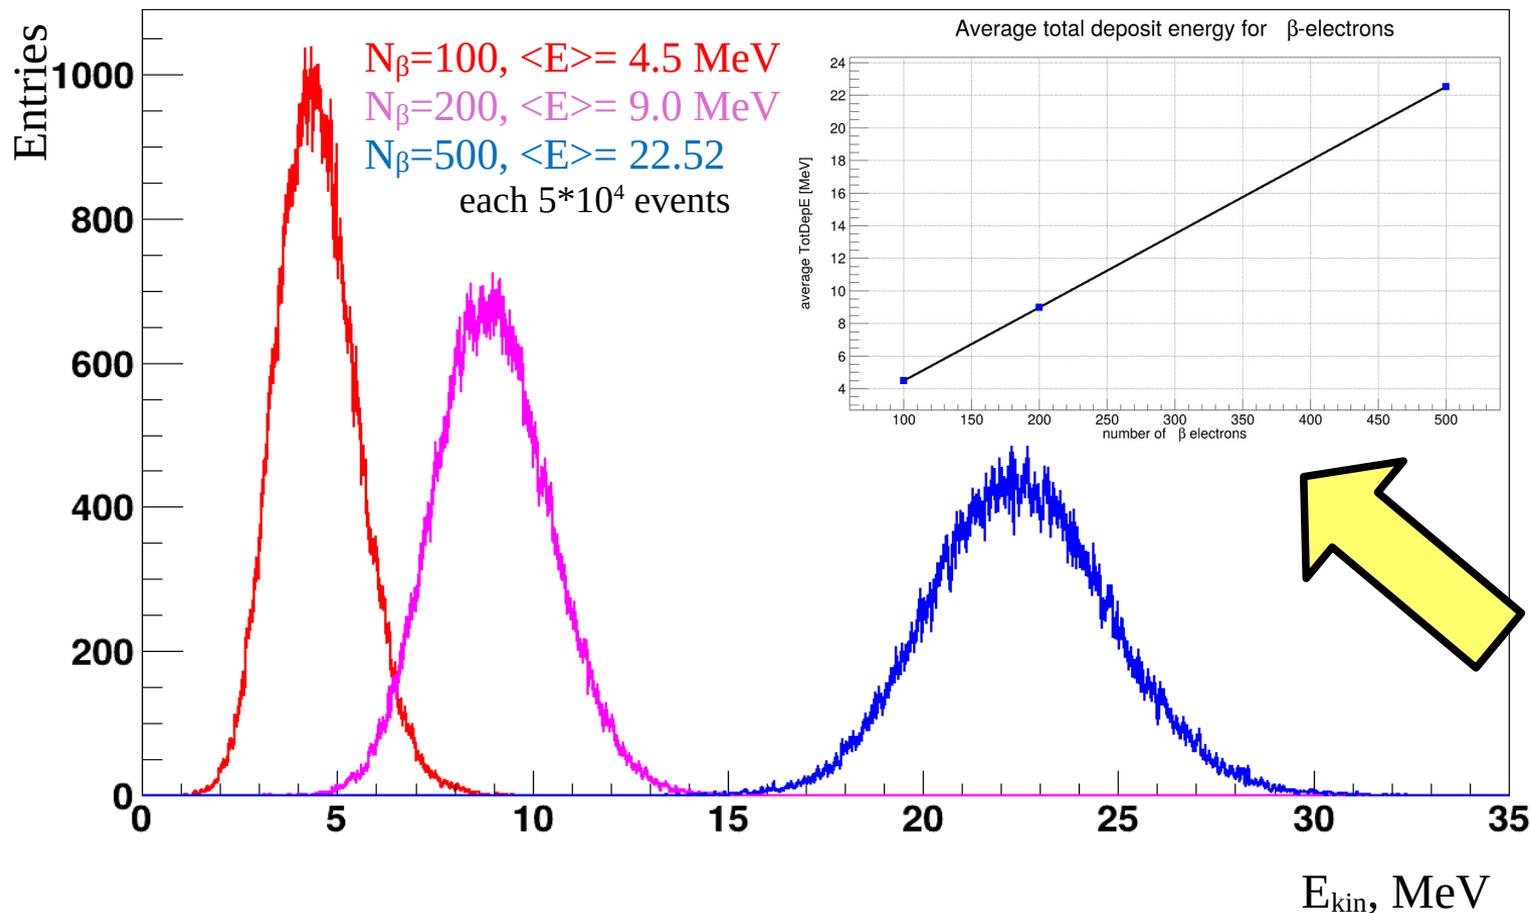

$\pi$ -beam

# Kinetic energy of $\beta$ - electrons from Sr-90

# Total $E_{\text{kin}}$ for $N_{\beta} = 100, 200$ and $500$ (No beam)

How many  $\beta$ 's do we need?

$$1 \text{ Ci} = 3.7 \cdot 10^{10} \text{ s}^{-1}$$

$$100 \text{ mCi} = 3.7 \cdot 10^9 \text{ s}^{-1}$$

$$4\pi \rightarrow 2\pi \rightarrow \sim 2 \cdot 10^9 \text{ s}^{-1}$$

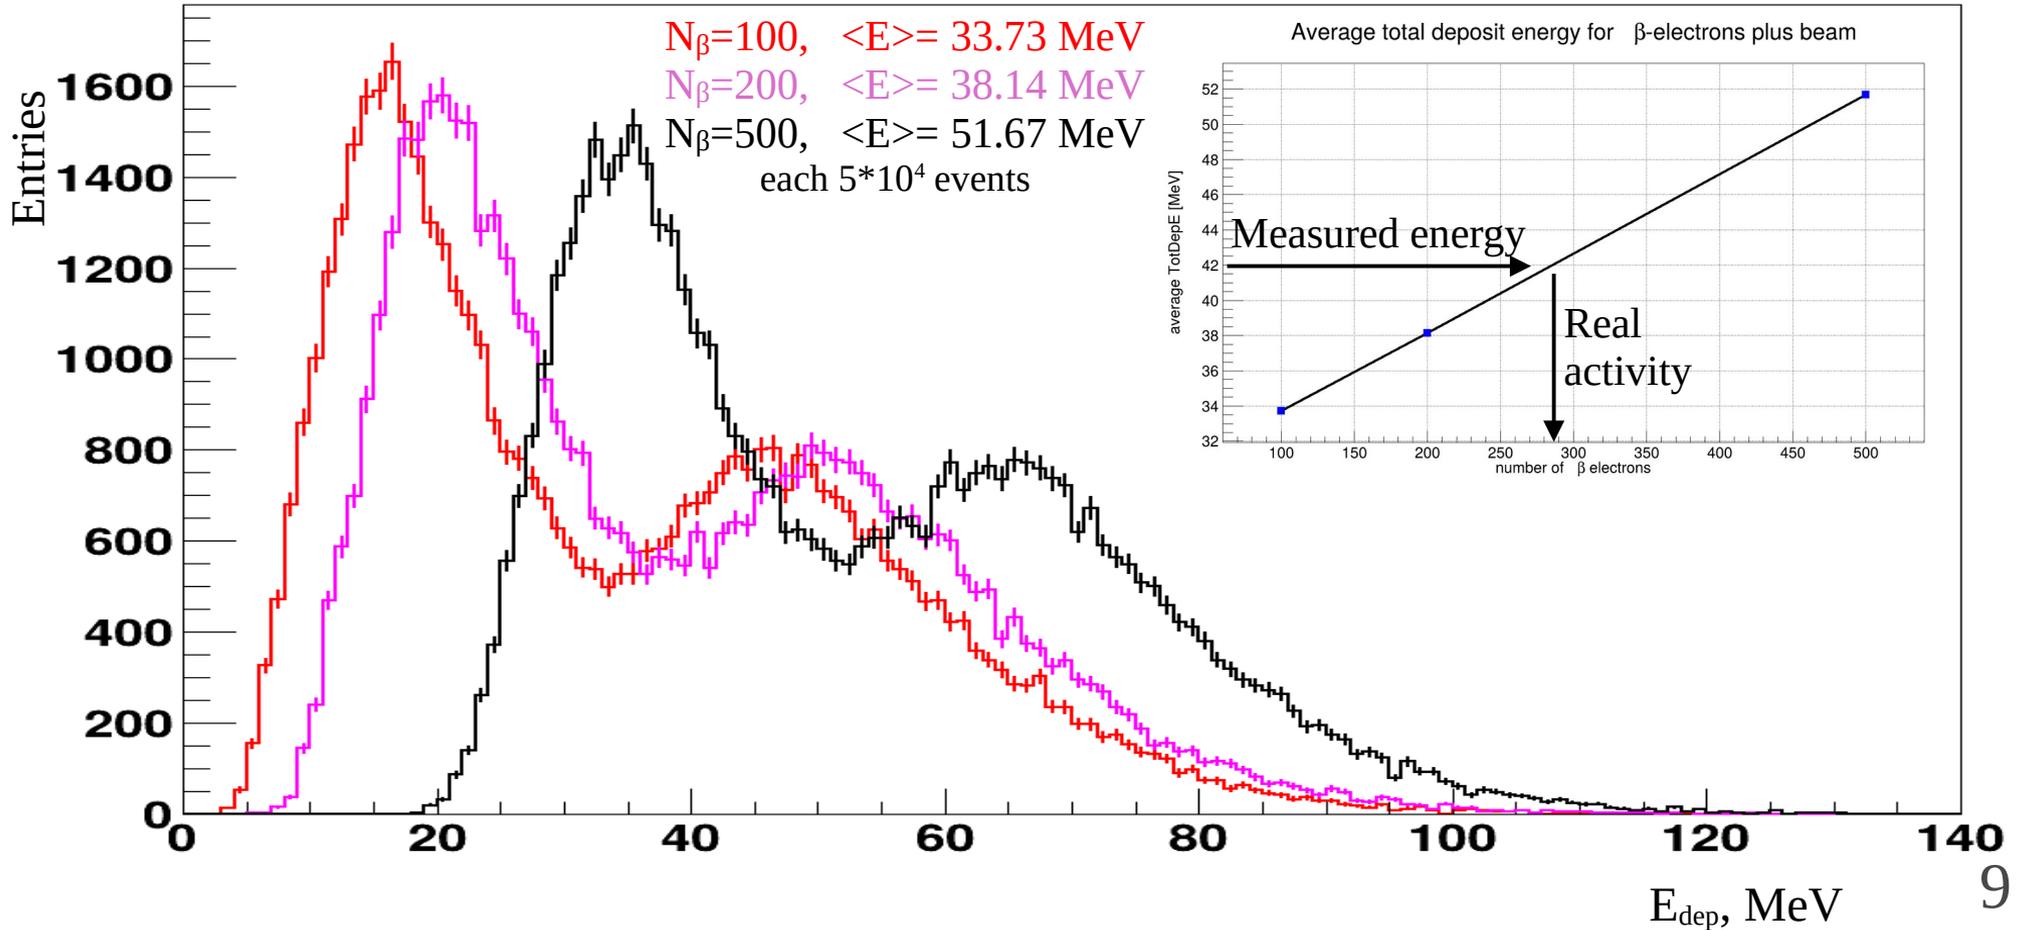

pulse duration in FCal is  $\sim 50 \text{ ns}$   
(LAr TDR)

We need  $\sim 100 \beta$ 's for every  $e^-$

Actual value of the source activity we could estimate by comparing experimental data and simulation for different  $N_{\beta}$

# Total deposited energy of the beam(180GeV) plus $\beta$ -electrons

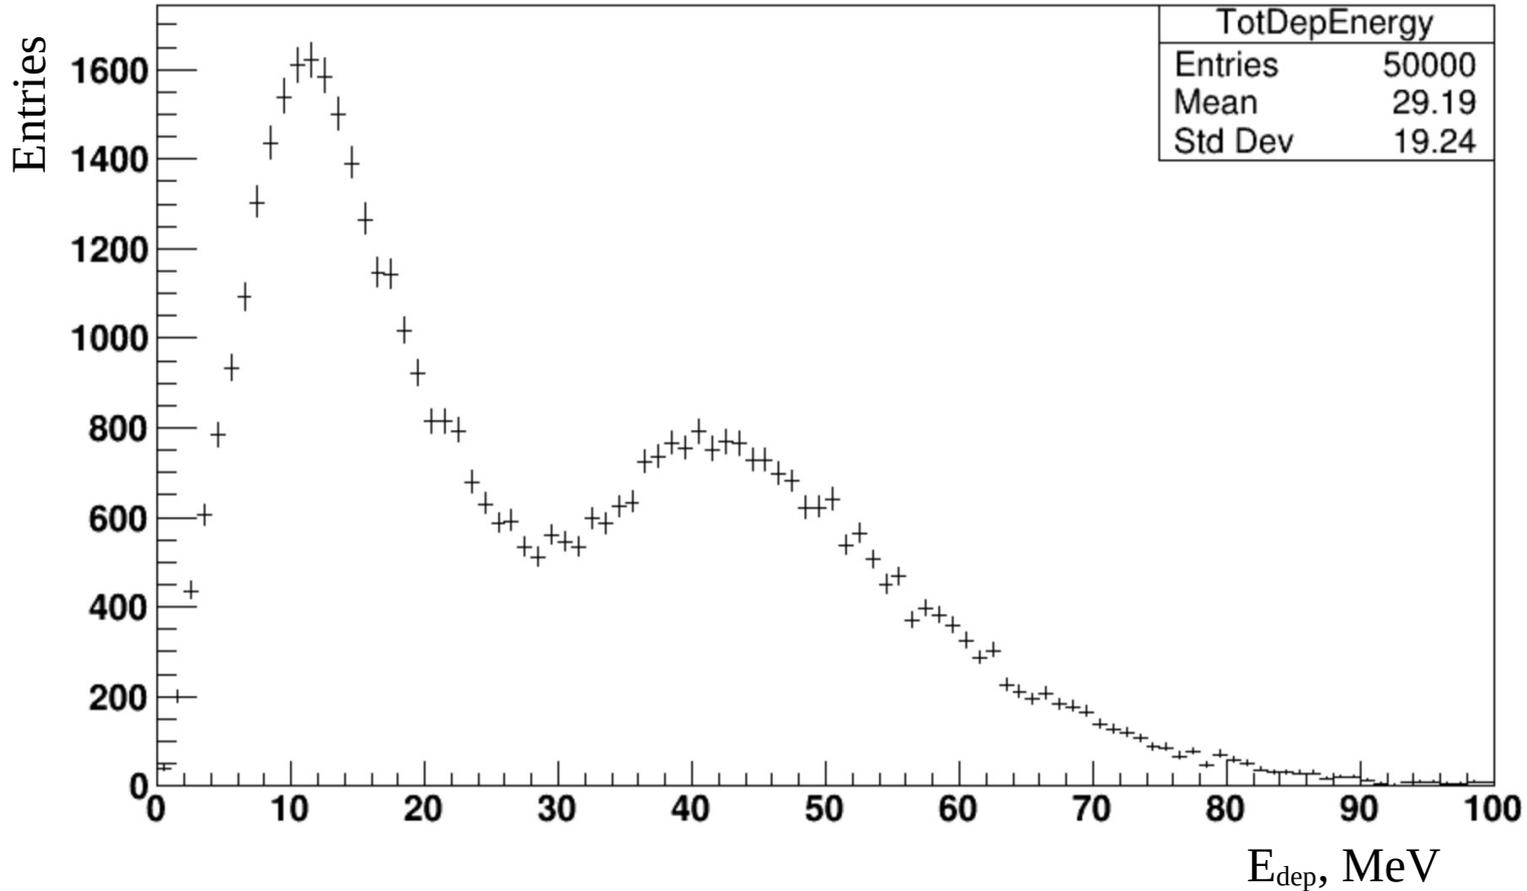

# Conclusion

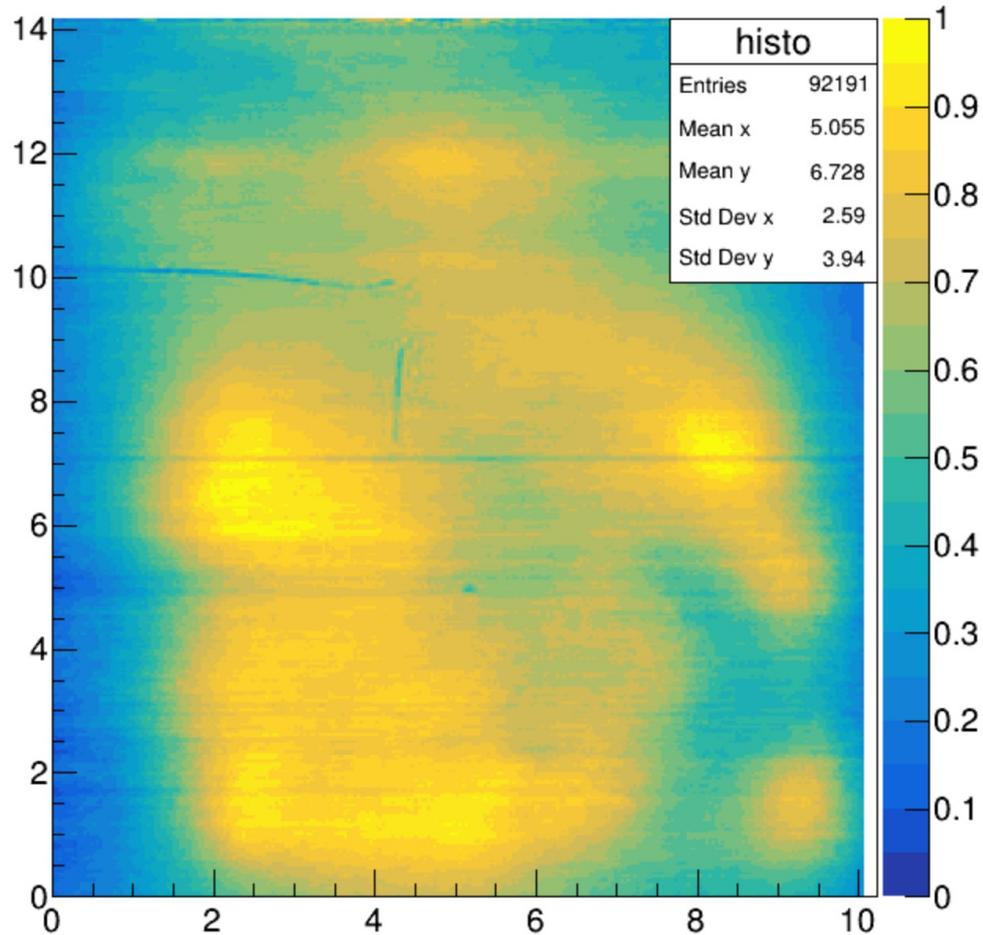

- Finally, we obtained deposited energy distributions for the test-beam setup with and without beta-source
- Sven's homework is done, but needs to be digested
- For further progress we need to decide on:
  - ◆ the actual geometry (beam spot size  $R$ )
  - ◆ number of beta-electrons (a range of?)
  - ◆ plots ?

**Back up**

# Total deposited energy for 180 GeV (no Sr-source)

# digital foil

# Arizona group results to 0 and 2.5 mm offset
