

# ***Stationary System for Magnetic Field Monitoring MPD Solenoid***

***(Current Design Status)***

***T.Bedareva, E.Antokhin***

## Introduction

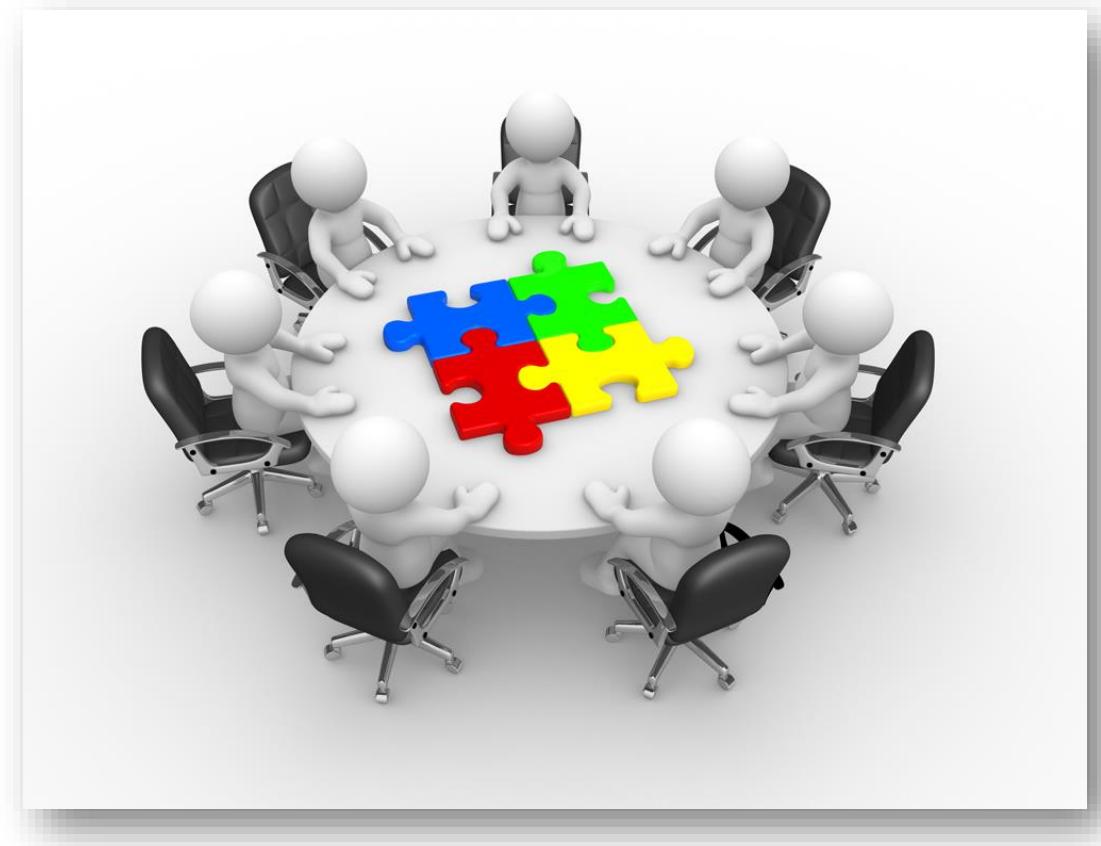

Any device used for scientific research is created in close cooperation between scientists and engineers. The stationary monitoring system is a joint project and involves a large group of specialists from BINP, Novosibirsk (Yu.Tikhonov, K. Zhilyaev, A. Pakhomov, P. Dovgerd, A. Klimenko etc.) and JINR, Dubna (V. Golovatyuk, K. Mukhin, S. Gerasimov, M. Buryakov, S. Buzin, etc.)

The design of any device directly depends on the equipment that will be used in the operation of this device in order to obtain the required level of measurements.

As a result of cooperation, a lot of pre-work has been done to test and compare different types of sensors from different manufacturers with the possibility of further use in this monitoring system.

This report is more of an overview in order to present the amount of preliminary work has been done.

In the future, the collaboration will move to a new level.

## General information

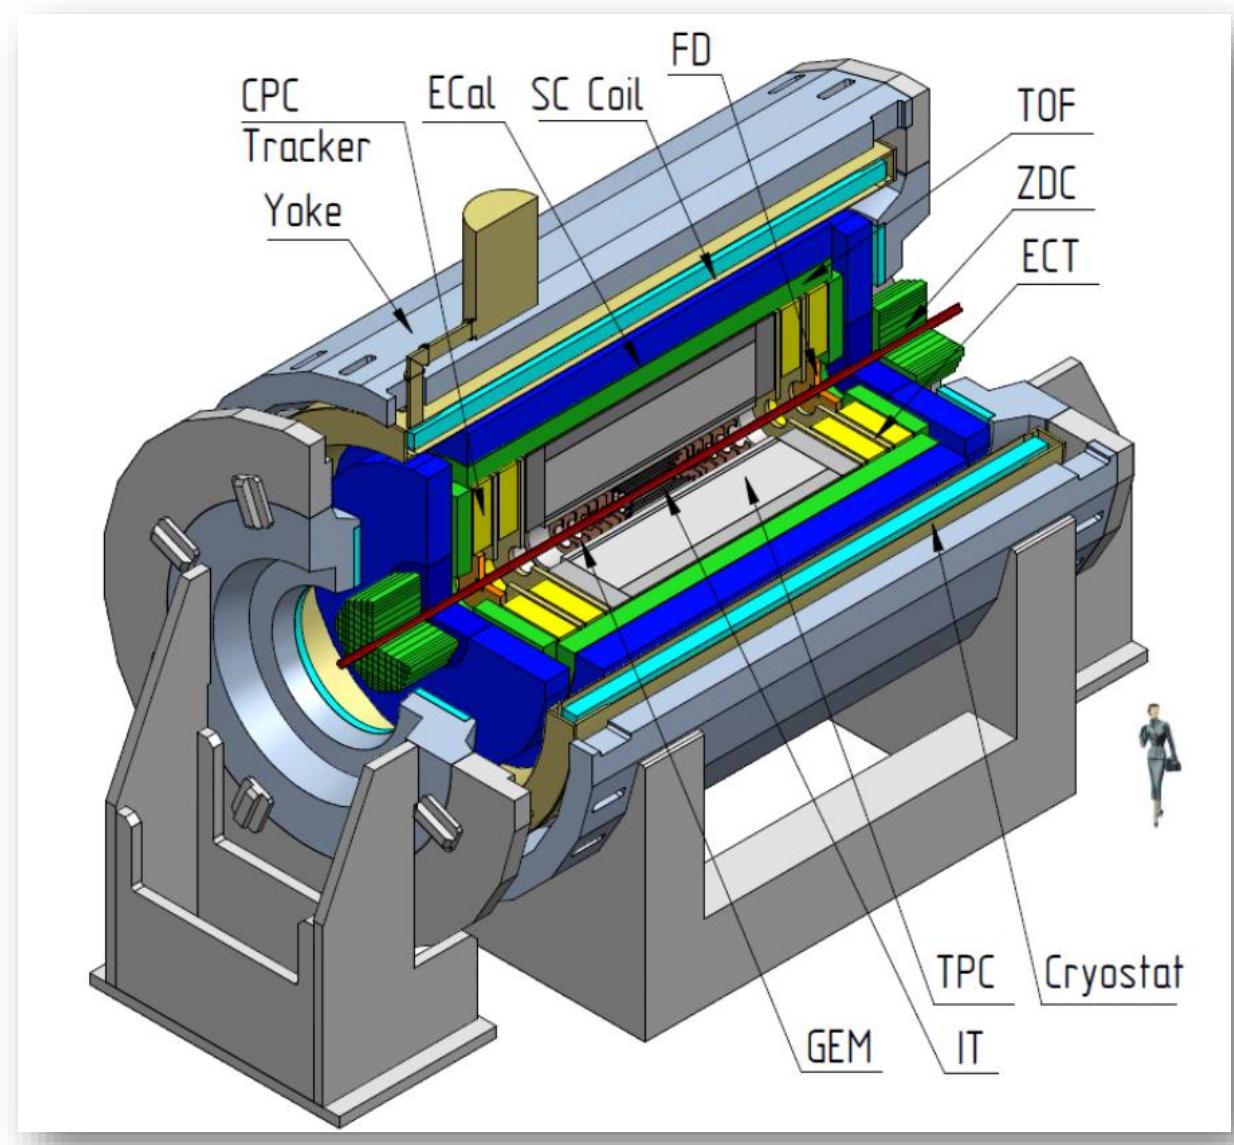

The Multi-Purpose Detector (MPD) superconducting solenoid magnet is designed to provide a highly homogeneous magnetic field of up to 0.57 T (with a default operational setting of 0.5 T).

Stationary Hall probes are installed in the MPD detector to monitor real magnetic field variations **from** the superconducting **and TRIM** coils of the detector.

Stationary Hall probes for magnetic field monitoring should be installed after all magnet tests with volume 3D mapper have been completed.

Stationary Hall probes will be calibrated based on the field measuring by 3D volume mapper.

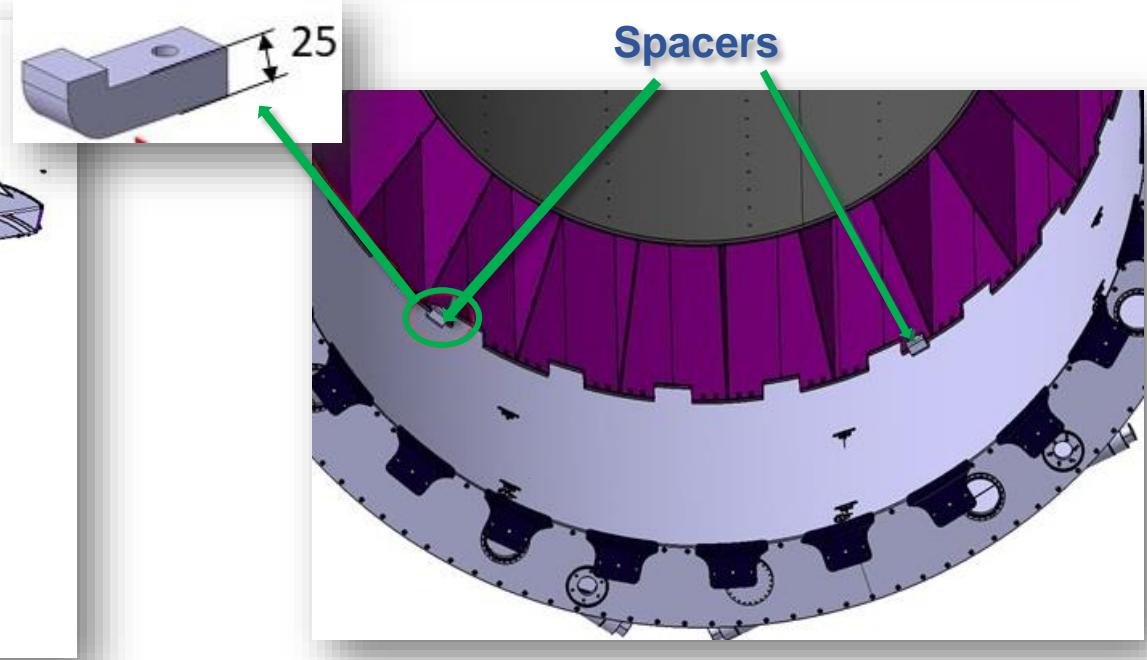

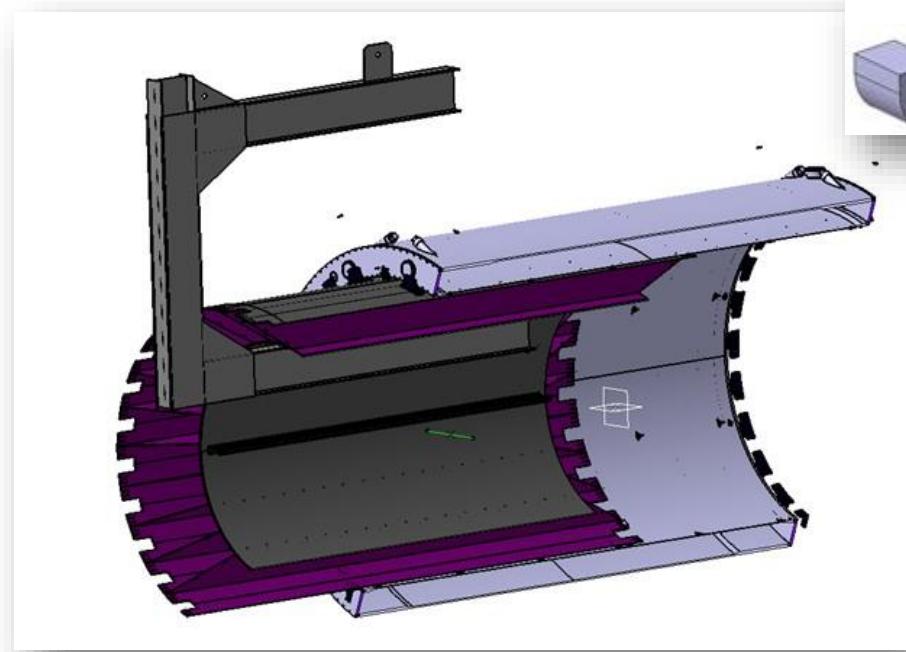

After long time the field map from 3D mapper may be slightly changed (due to hysteresis, SC coil shifts and etc.). Thus 3D field map can be corrected using the data from stationary Hall probes.

The overall dimensions of the stationary system elements are determined by free space between cryostat and MPD power frame, on which the detector internal components are mounted.

For more information about magnet field stationary Hall probes shall be installed in the area of largest  $B_r$  component variation. i.e. at the outer radius at edge of SC coil.

It is planned to use spacers during installation work to avoid damage to the stationary system elements.

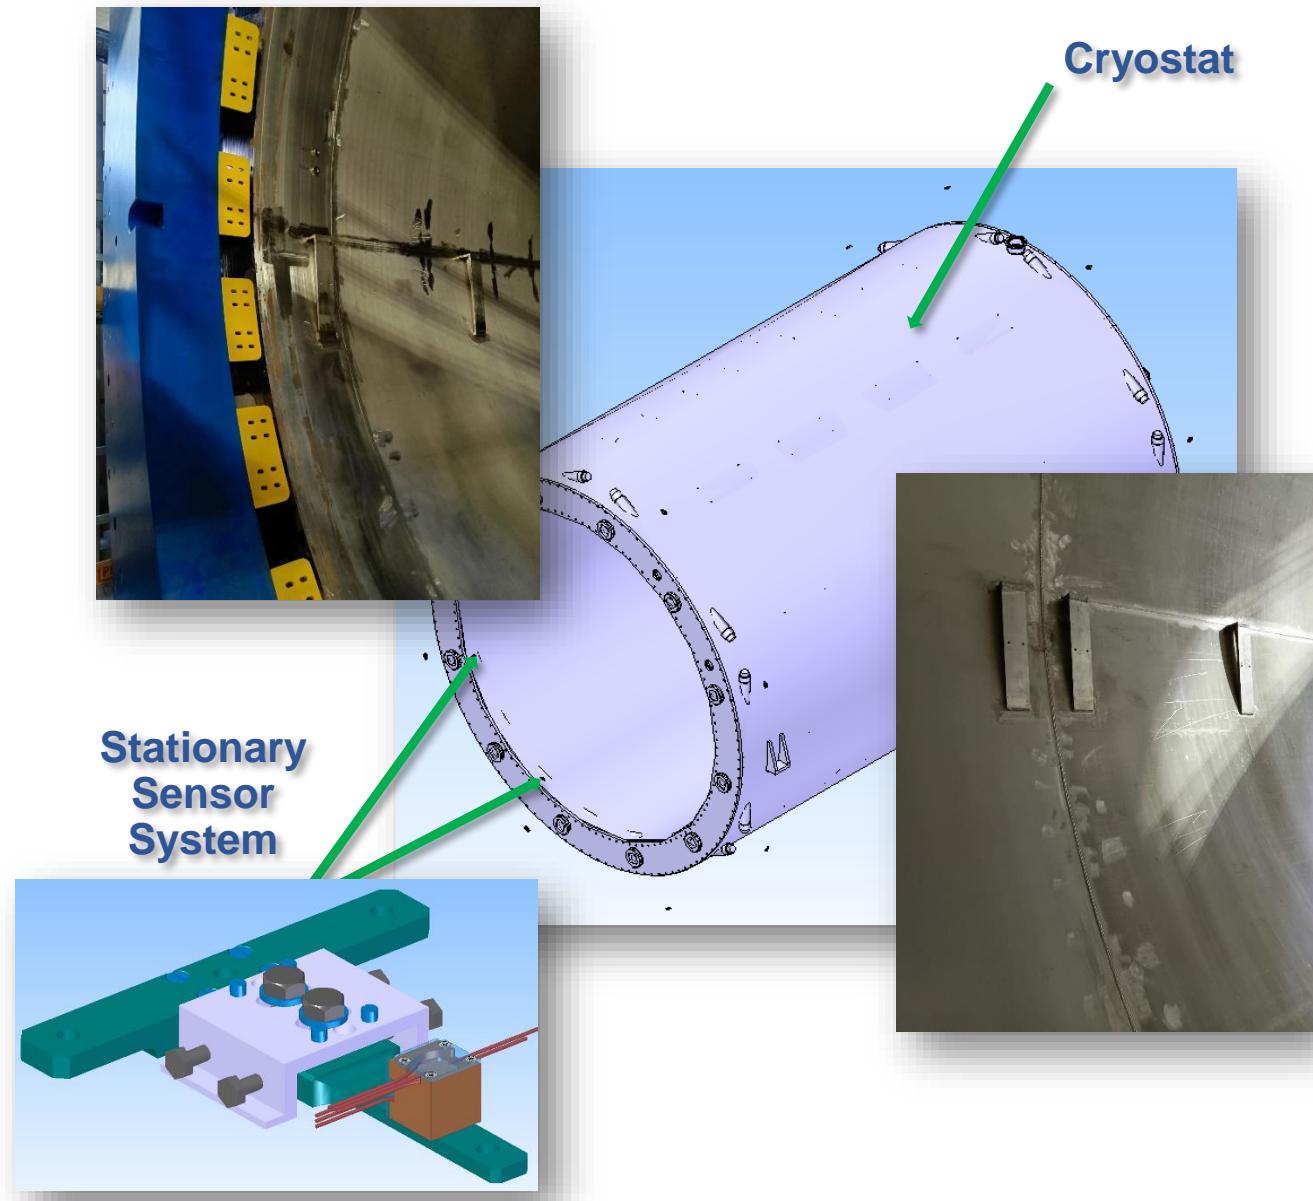

The MPD stationary magnetic field monitoring sensors should be installed in such a way as to avoid damaging them during the process of installing the MPD power frame in the cryostat.

It is assumed to install the sensors of the stationary monitoring system on the surface of the inner wall of the cryostat, where they are as far from the chamber axis as possible. The sensors will be placed in the center zone of the detector (equidistant from the edges) and on the edges of the detector inside the chamber at a distance of 200 mm from the ends.

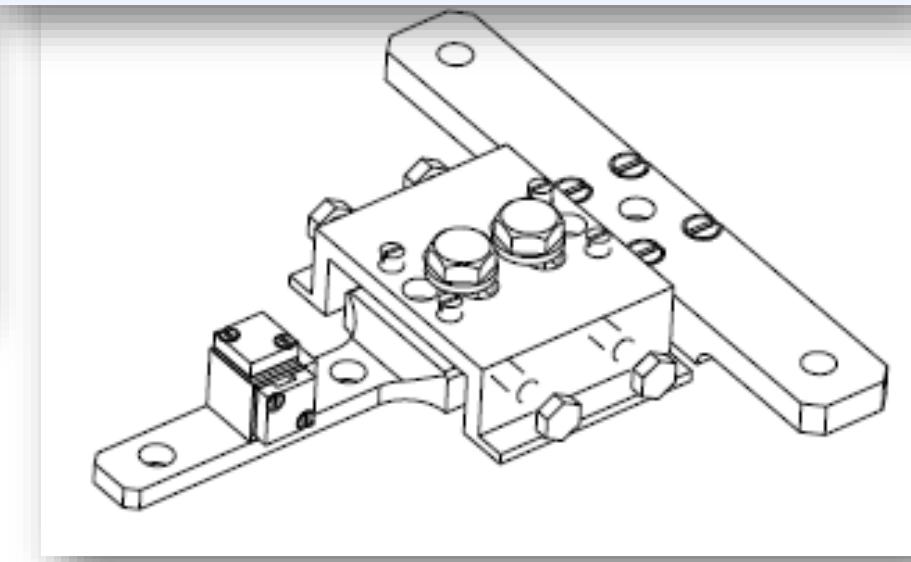

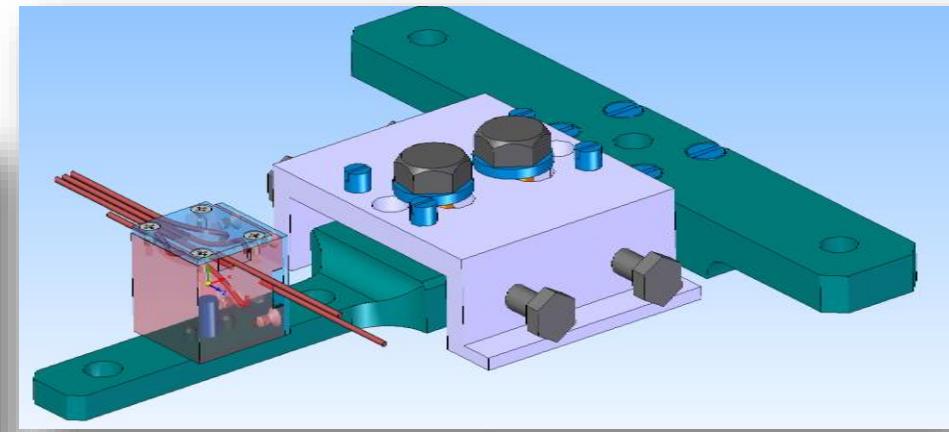

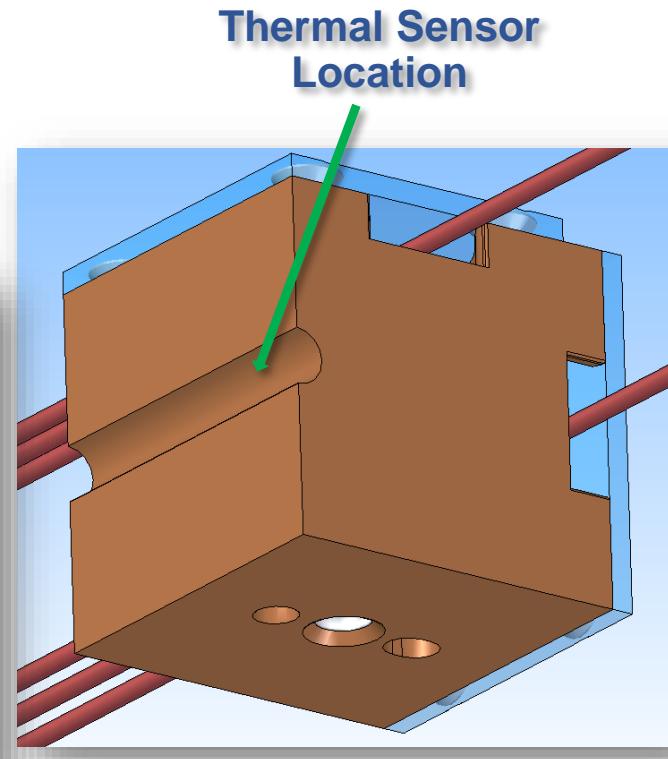

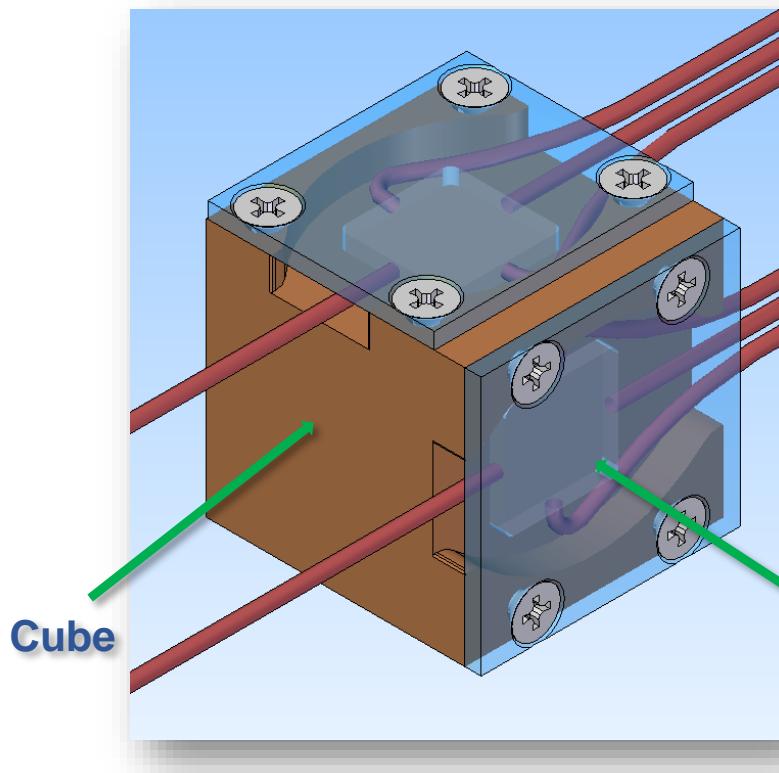

In the central area, the sensors are placed at  $90^\circ$  - 4 sensor intervals. Sensors at the edges of the measurement zone are placed at  $45^\circ$  intervals, i.e. 16 sensors on each side of the detector. A total of 36 sensors are used to monitor the entire volume.

## Stationary Sensors System Design

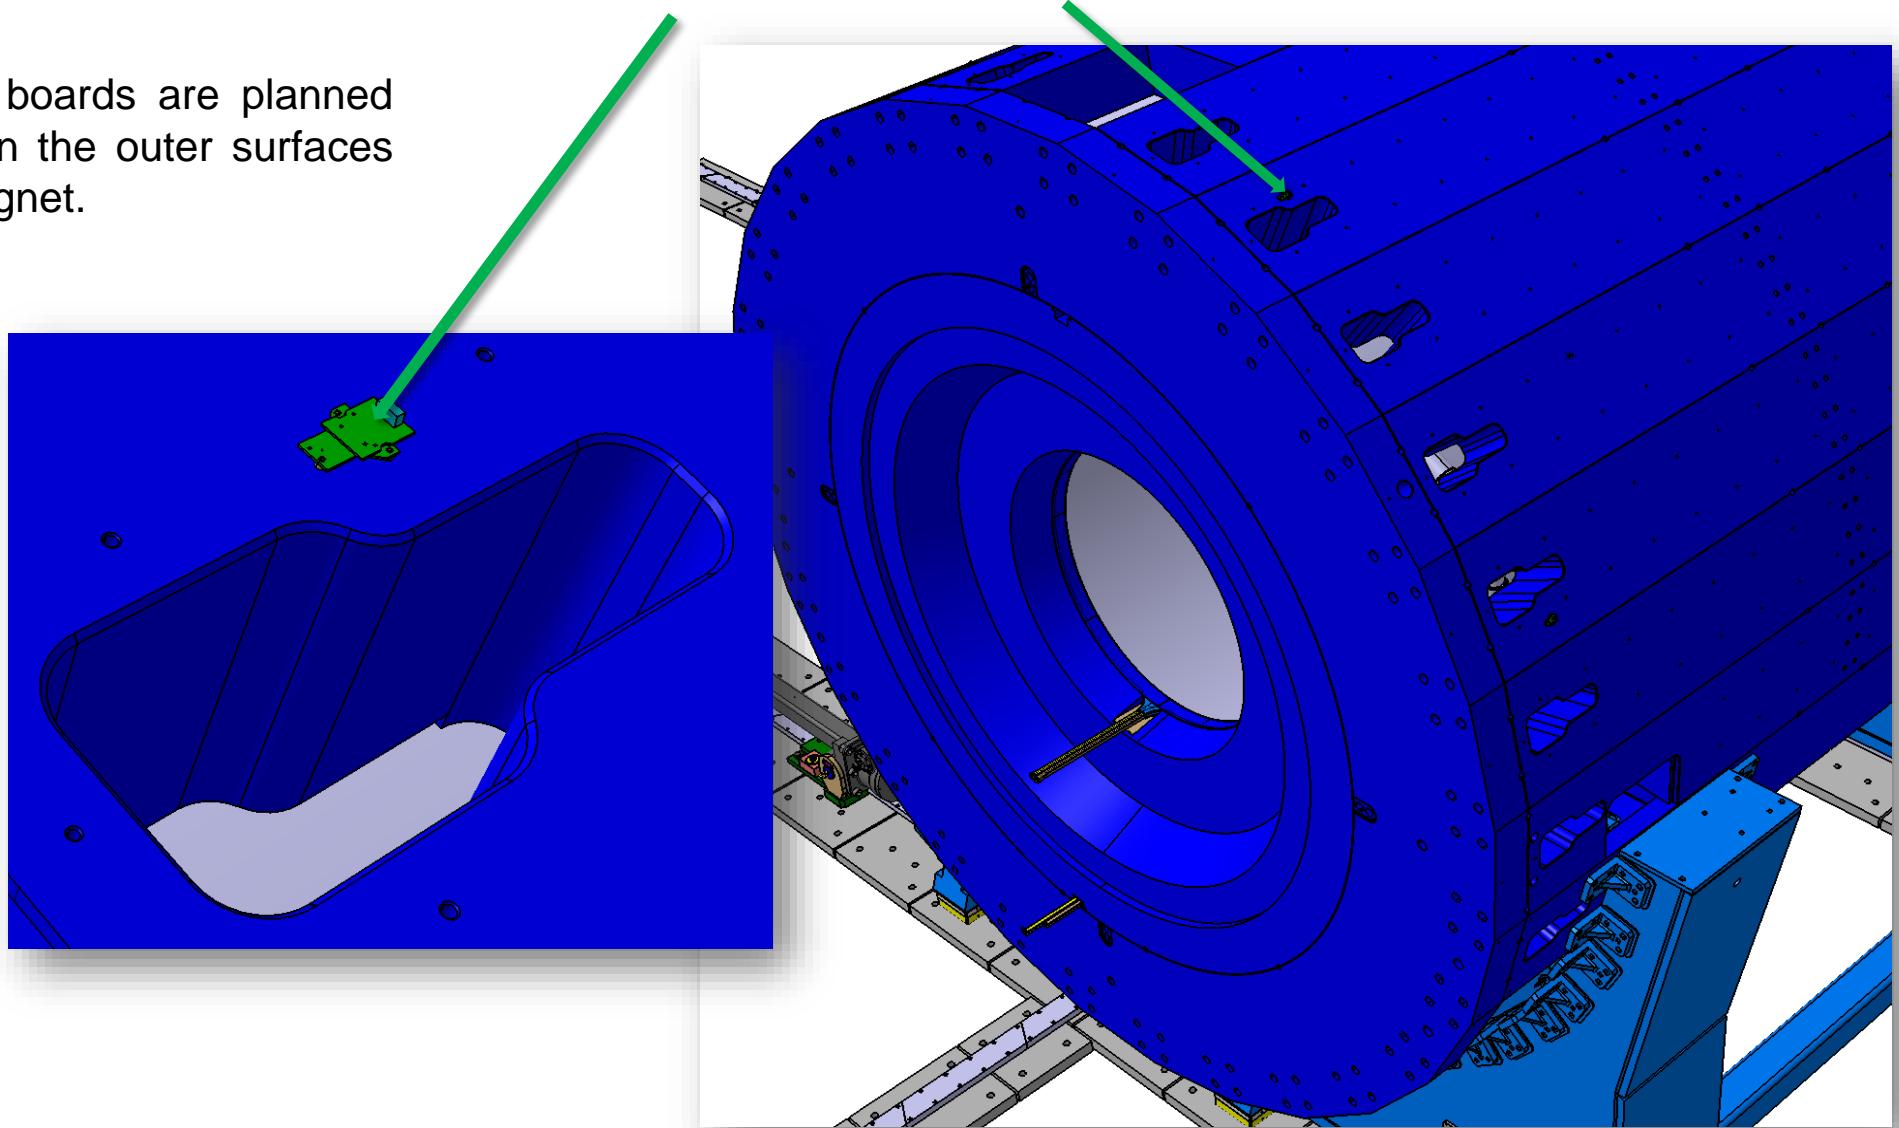

The sensor stationary monitoring system includes a cube for Hall probes and devices for the cube fixation and mounting this system to a cryostat inner wall.

The electronic boards are planned to be placed on the outer surfaces of the MPD magnet.

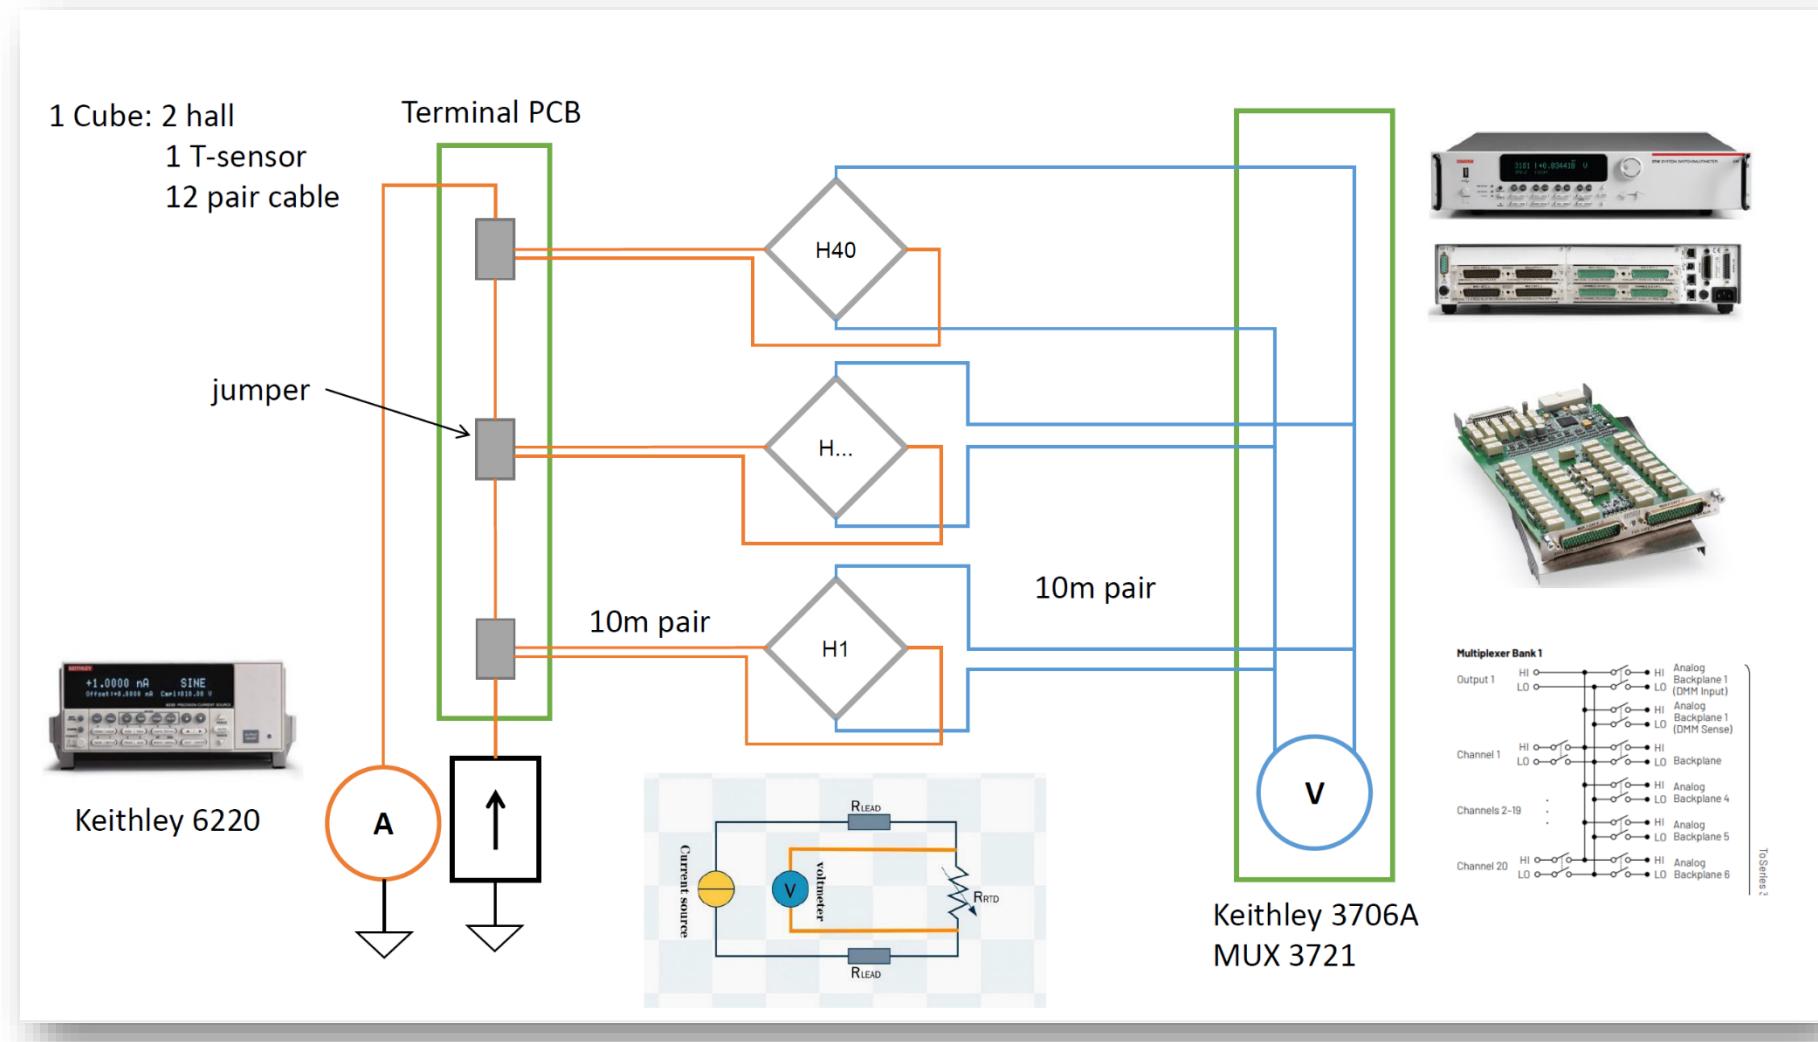

Electronic Boards

## **Commutation Scheme**

Hall probes  
commutation with  
nano voltmeter and  
commutator inside  
MPD solenoid.

# Commutation Scheme was provided by M.Buryakov and S.Buzin (JINR, Dubna)

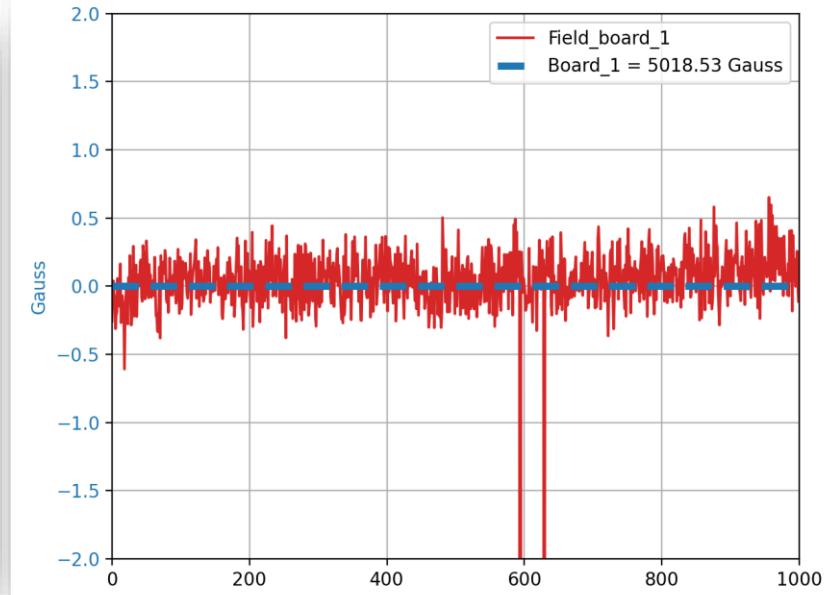

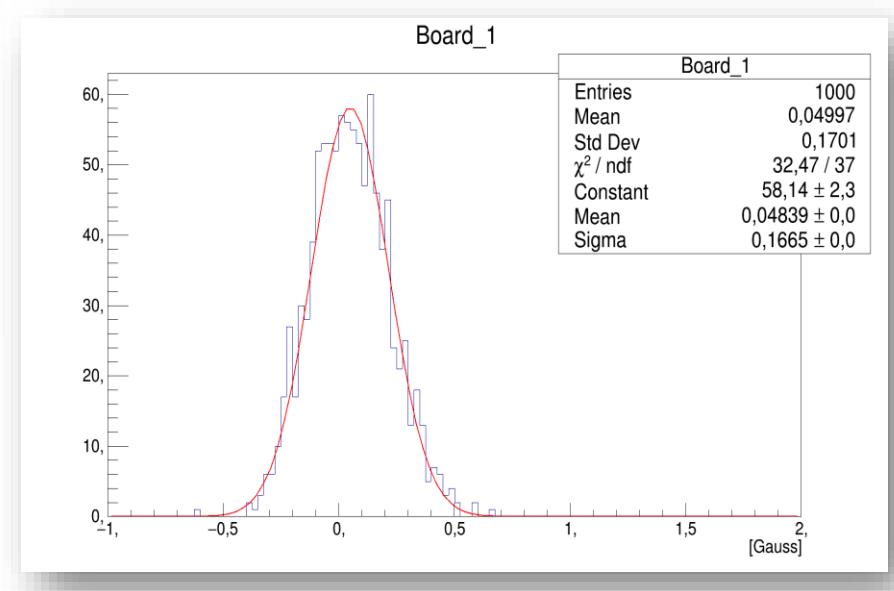

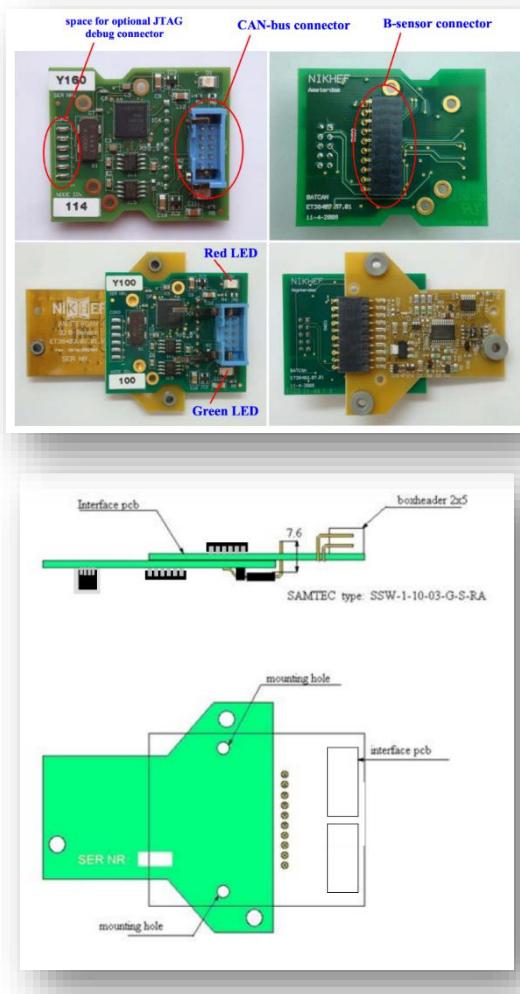

# Sensors Verification: Electronic Boards

M. Buryakov, S. Buzin (JINR, Dubna)

The existing in JINR electronic boards will be used in a monitoring field system for MPD magnet. Each board has 3D Hall probe and own analog-digital converter. Digitization allows transfer signal to long distance.

Measurements of noise were done and found out as  $\pm 0.5$  Gs.  
That is out of specification for field monitoring.

For detailed information on sensor verification please  
contact M.Buryakov and S.Buzin (JINR, Dubna)

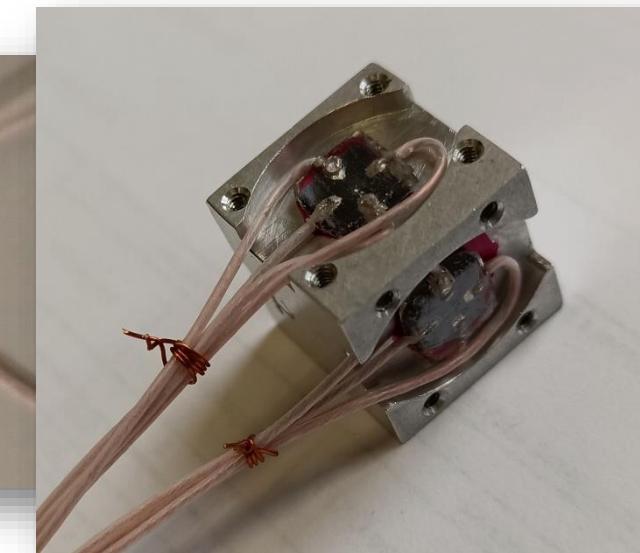

## Sensors Verification: *Nizhniy Novgorod State University Hall probes*

45 Hall probes were developed and produced for MPD magnet field monitoring with high parameters as:

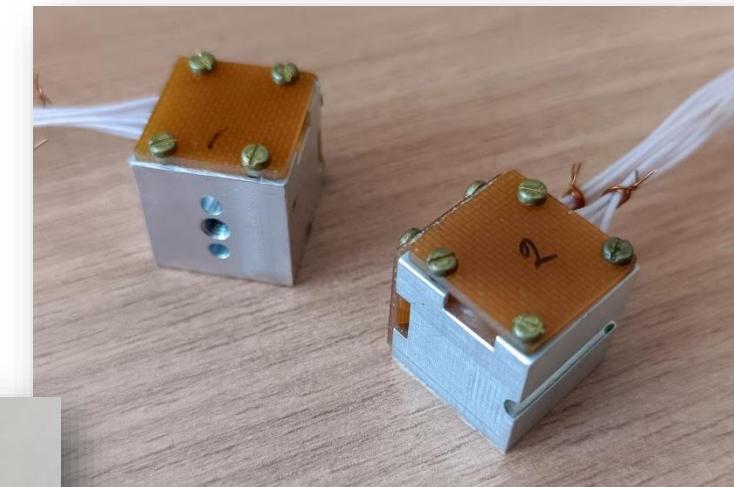

Aluminum sample

Hall  
sensor

Magnetic sensitivity	15 mkV/Gs
Temperature coefficient of magnetic sensitivity	$\leq 0,01\%/\text{C}$
Residual voltage	100 mkV
Temperature coefficient of residual voltage	1-2 mkV/C (or 0,05-0,1 Gs/C)

Hall probes installed onto aluminum base for measuring Bz and Br components of the MPD solenoid.

# Sensors Verification: Nizhniy Novgorod State University Hall probes data measuring

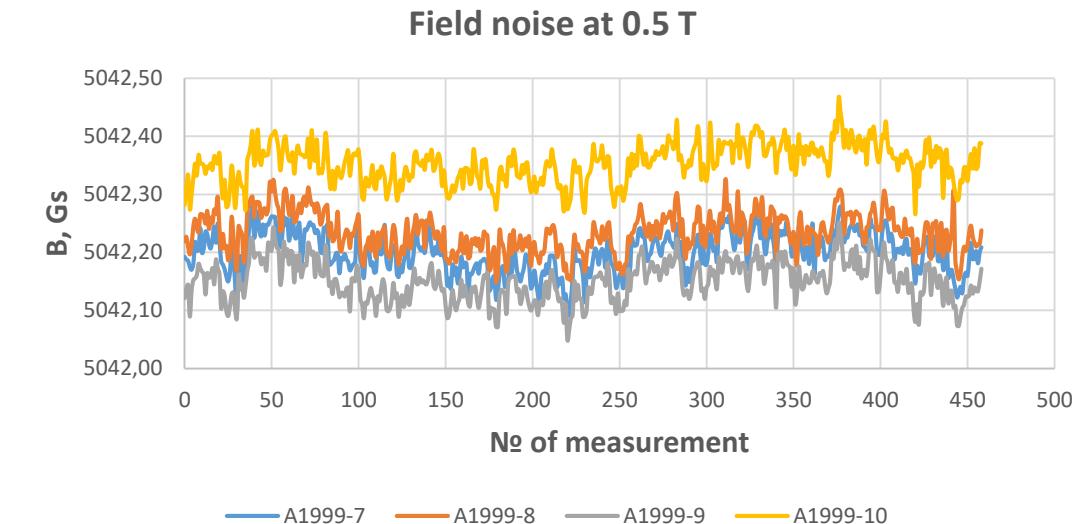

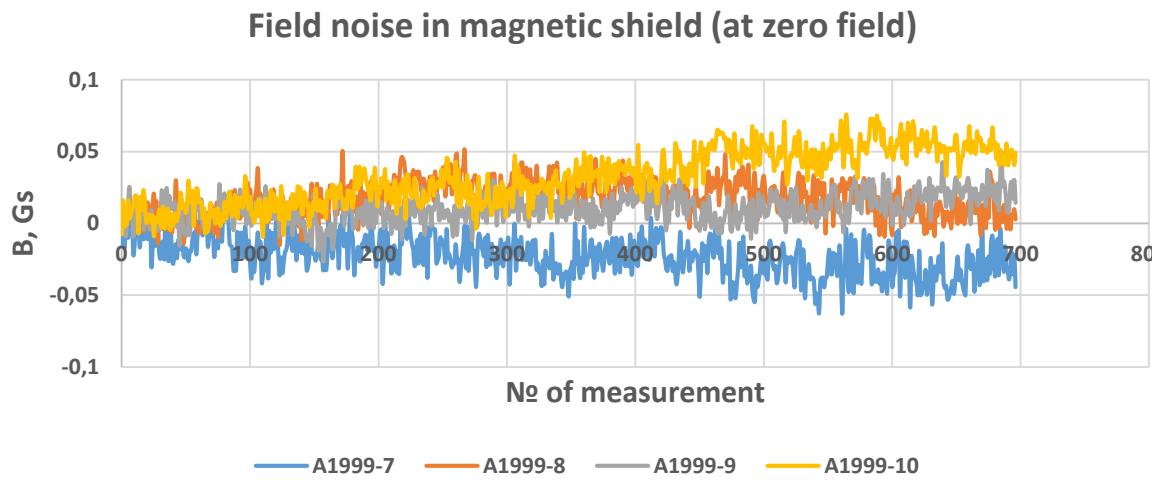

A.Pakhomov, K.Zhilyaev (BINP, Novosibirsk)

# Sensors Verification: Nizhniy Novgorod State University Hall probes noise study

## A. Pakhomov (BINP, Novosibirsk)

Hall probes noise is about  $\pm 0.1$  Gs. Well suitable for MPD magnet monitoring.  
To keep the total system noise at this level we have to use the nano voltmeter  
with commutator!

**For detailed information on sensor verification please  
contact A.Pakhomov and K.Zhilyaev (BINP,  
Novosibirsk)**

***Thank you for your  
attention!***
