

Status and Considerations for
Mass Production and
Hyperon Flow Feasibility Studies

Nikolay Geraksiev

08.06.2018

- * Hyperon Flow Studies require massive statistics.
What is considered “mass production”?
(1 million is definitely not enough for
detailed flow studies, let alone hyperon flow studies)

- * How is it done? What is the request procedure?
Who does it? On what versions, models, details?
What is a reasonable request (time, size, etc.)?

- * Models (which? At least 2, UrQMD, LaQGSM)
Energies (at least 3, e.g. 4, 7, 9, 11 GeV)

Some considerations and details follow...

Considerations...

- * GEANT4 for FHCAL

- * New TOF sigma (80 ps) for better PID?
(e.g. high pT Kaons)

- * Most FHCAL unneeded mctracks have been removed,
so RECO files are much, much smaller.
Is the crash with TOF point and missing FHCAL mctrack
still there? My version still has it.

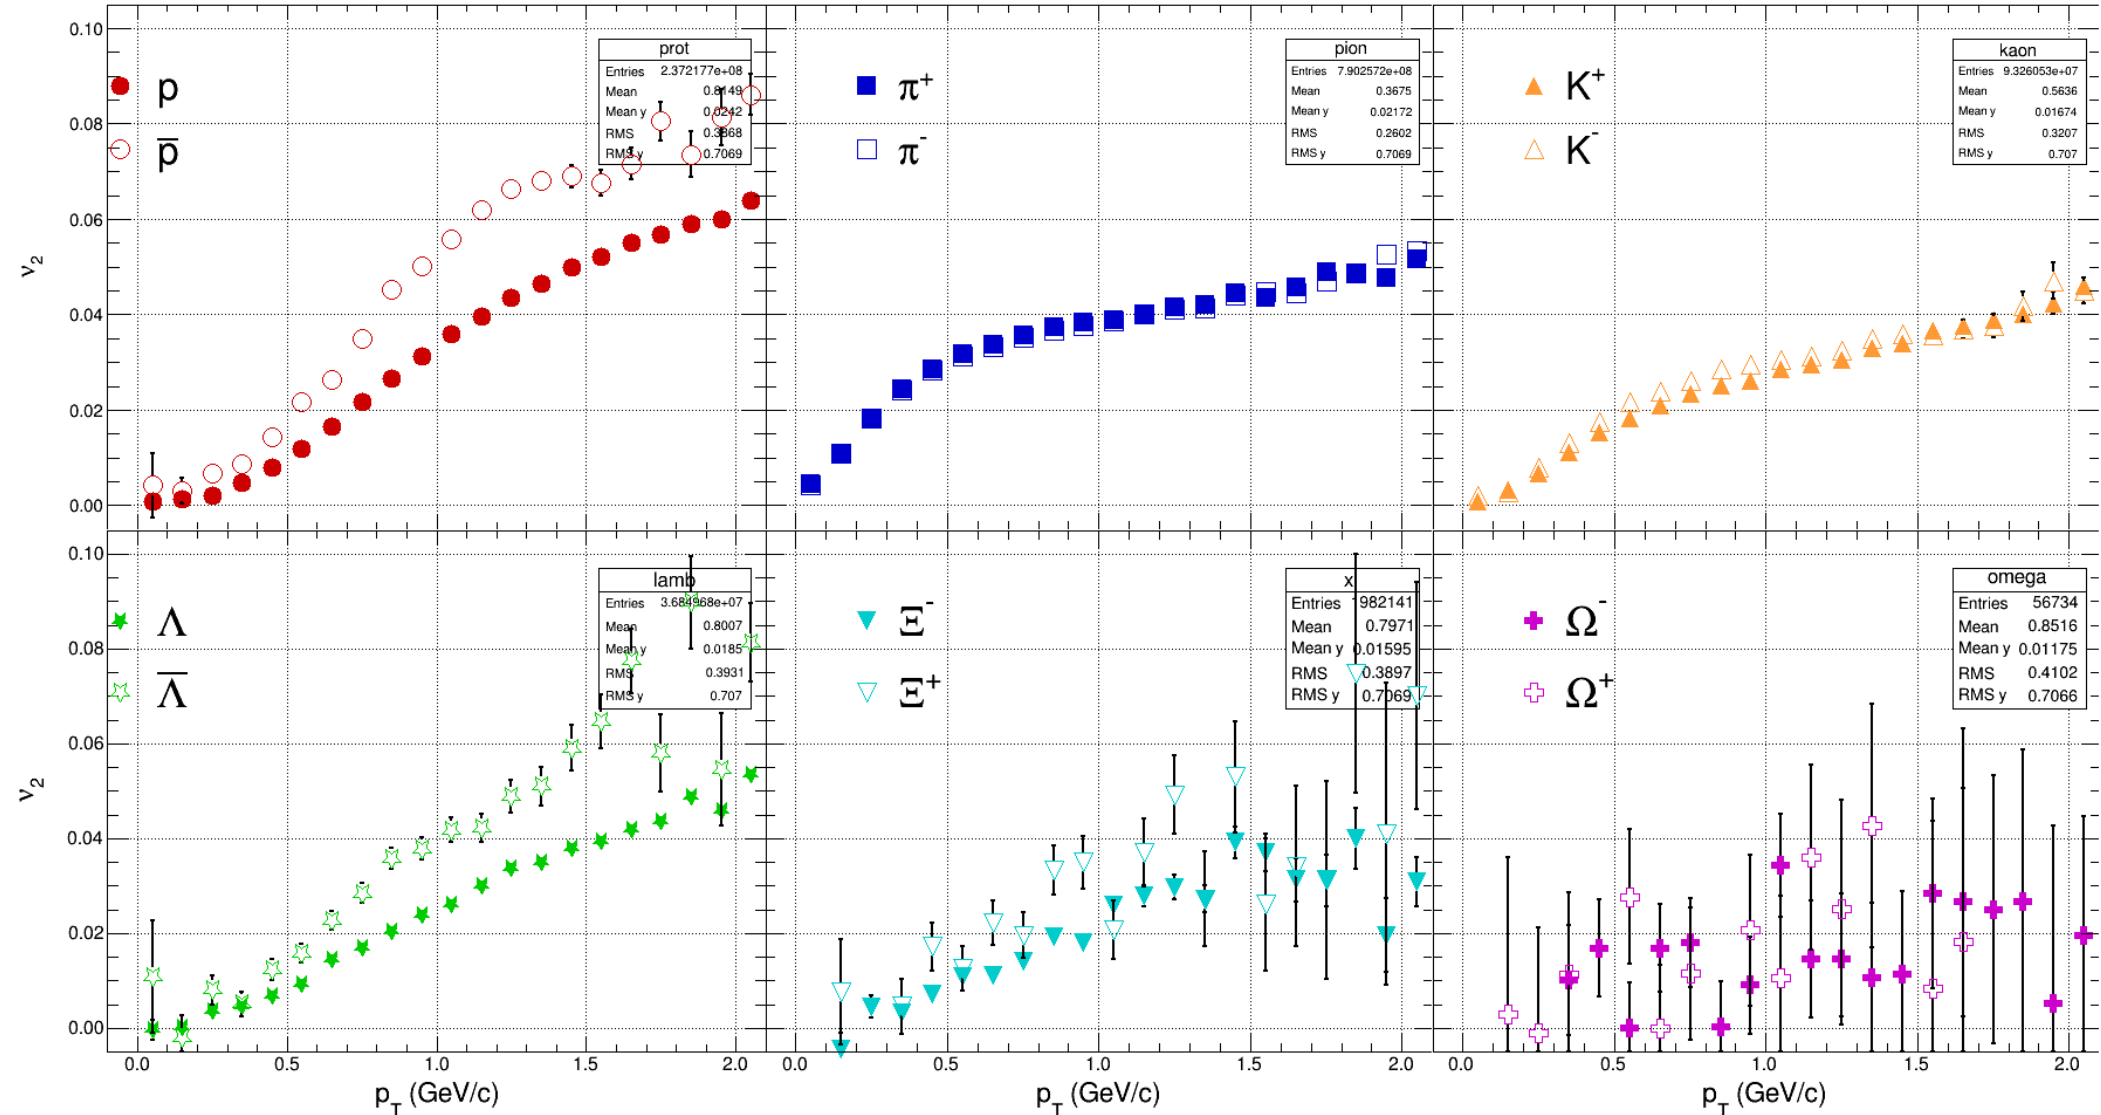

... considerations...

- * Event selection based on presence of particles of interest in the model?
(downside is less BG from events without POI)
- * Additional reduction of DST? Pico DST?
(Good idea but MpdParticle Reco requires full tracks)
(AFAIK)

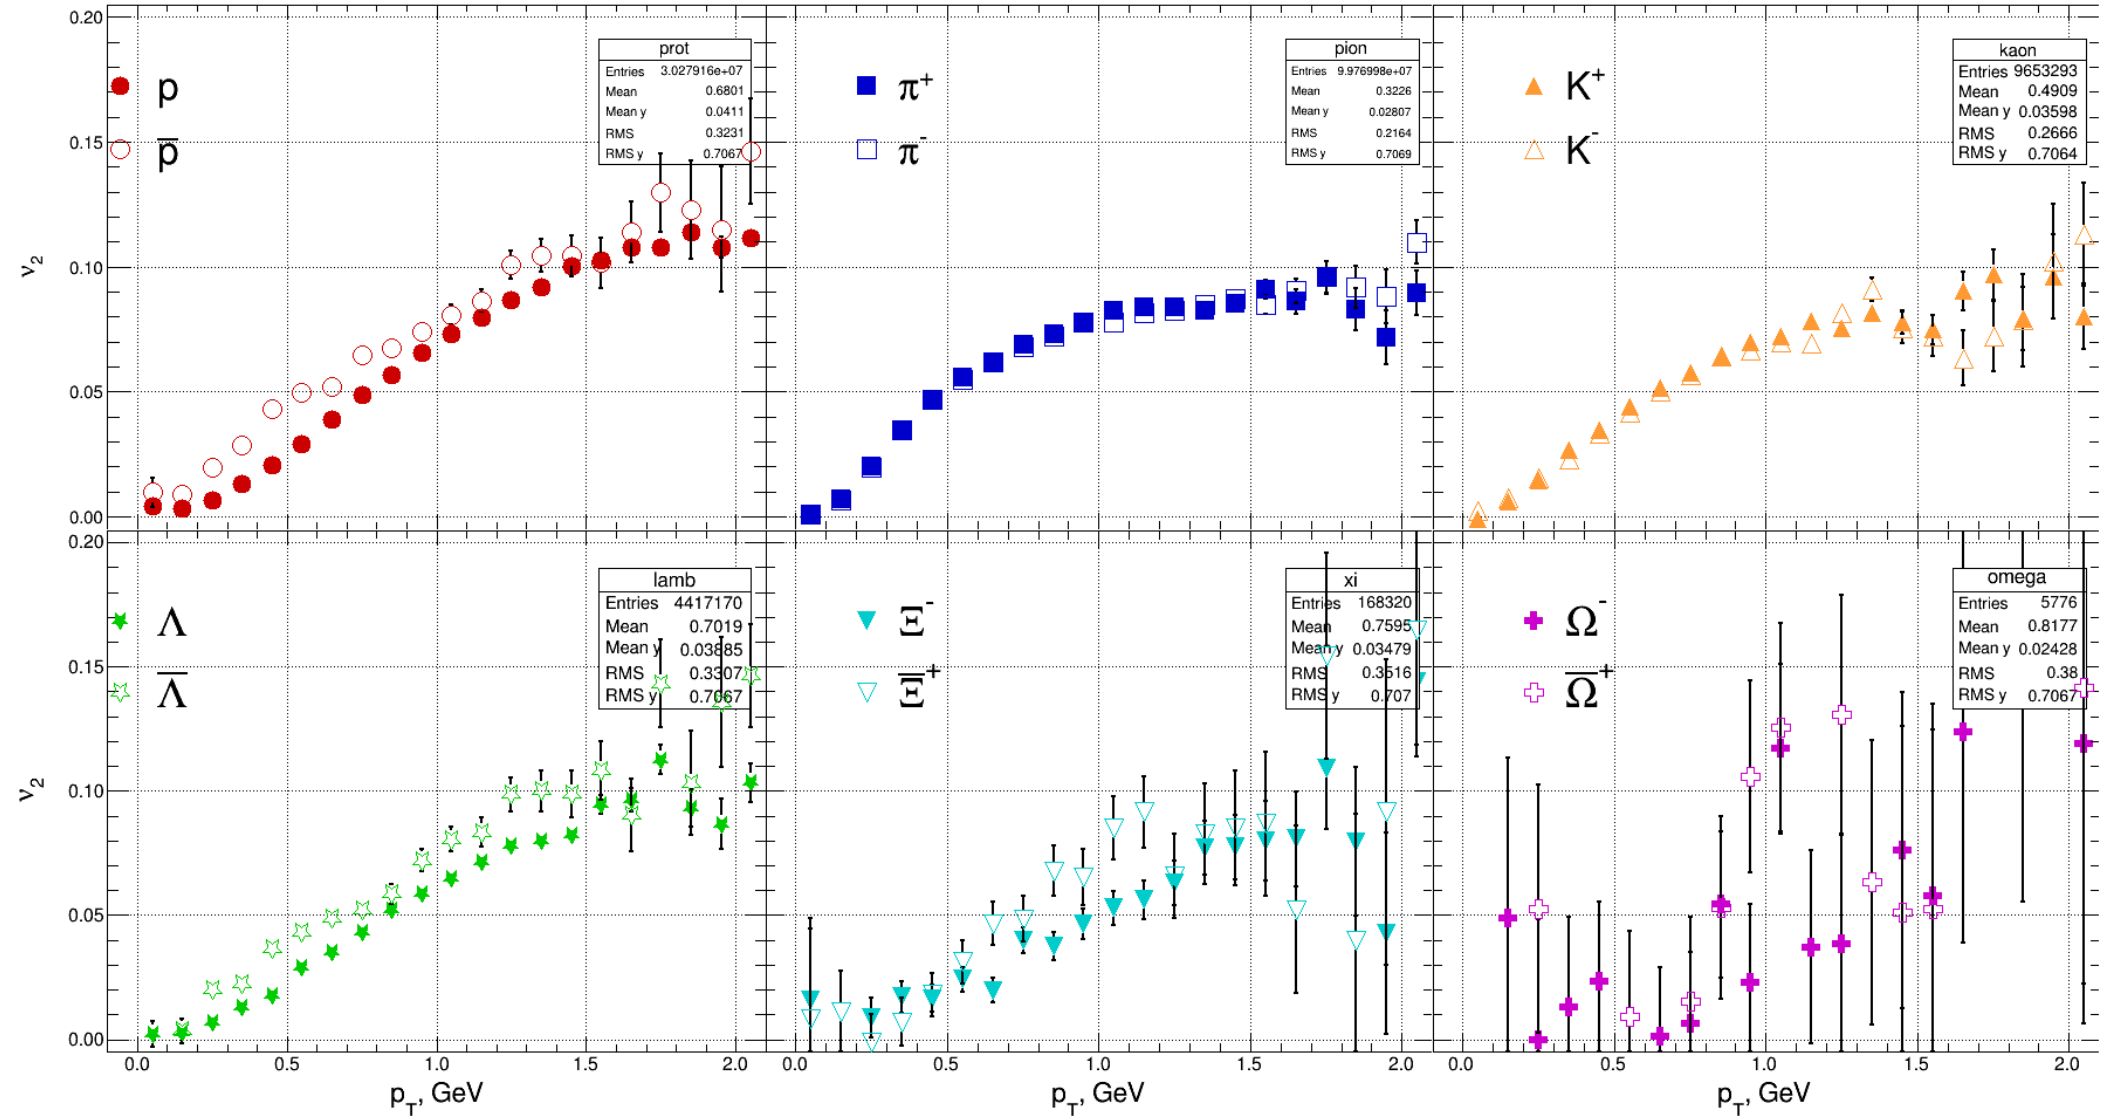

* Interactive NICA Cluster has been running worse recently (past week)
Limit of 50 qsub tasks on NICA Cluster.
Limit in storage space on NC.

* TPC Cluster Digitizer and MLEM Finder should be ported to GPU for (much) faster run time.
(Current Digi version porting to CUDA started, progress is slow)
(Previous Digi CUDA version has shown order of magnitude speed up)

Model in MPD acceptance: UrQMD(non-hydro): AuAu, 10 mil events, 11 GeV, 0..16 fm

Model in MPD acceptance: AMPT sm: 1 mil events, 11 GeV 0..16 fm

Hyperon Reconstruction

- Reconstruction efficiency is also important and not so good in previously shown results. (2013-2014)
- Results have improved for Lambda but are there newer Xi and Omega results?

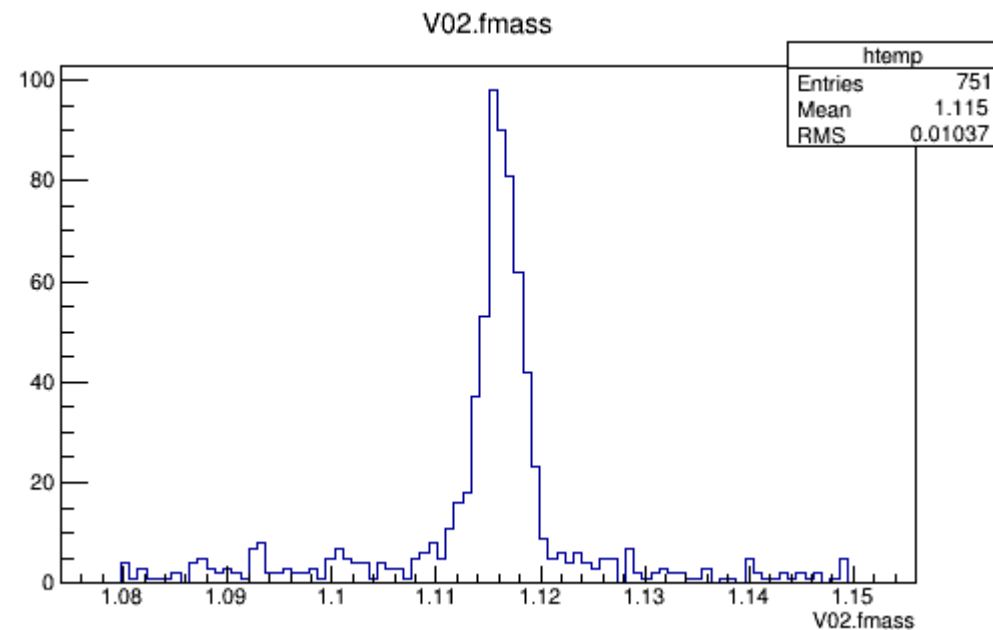

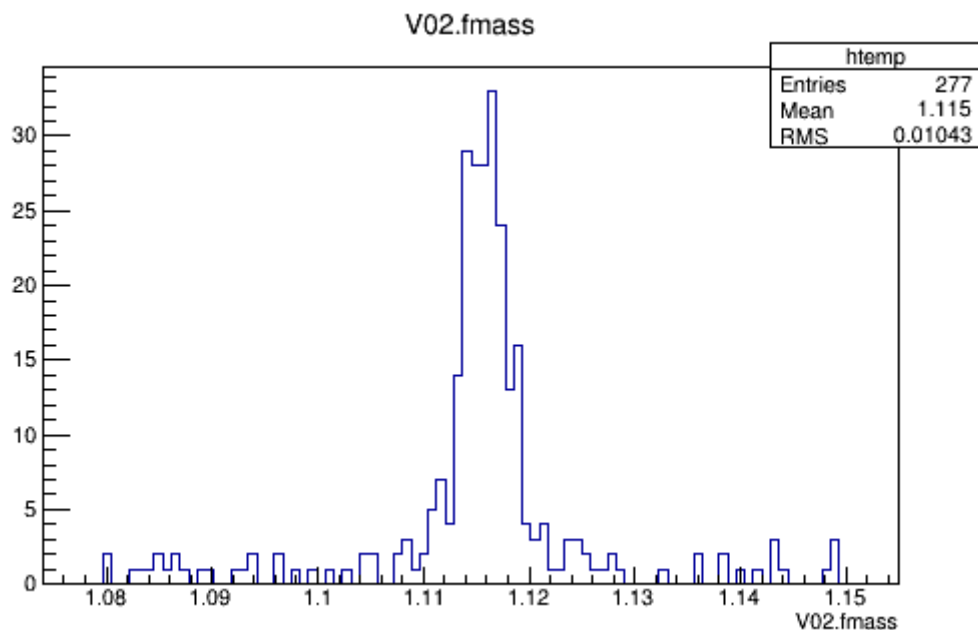

(with latest geometry and PID and MpdParticle algorithm)

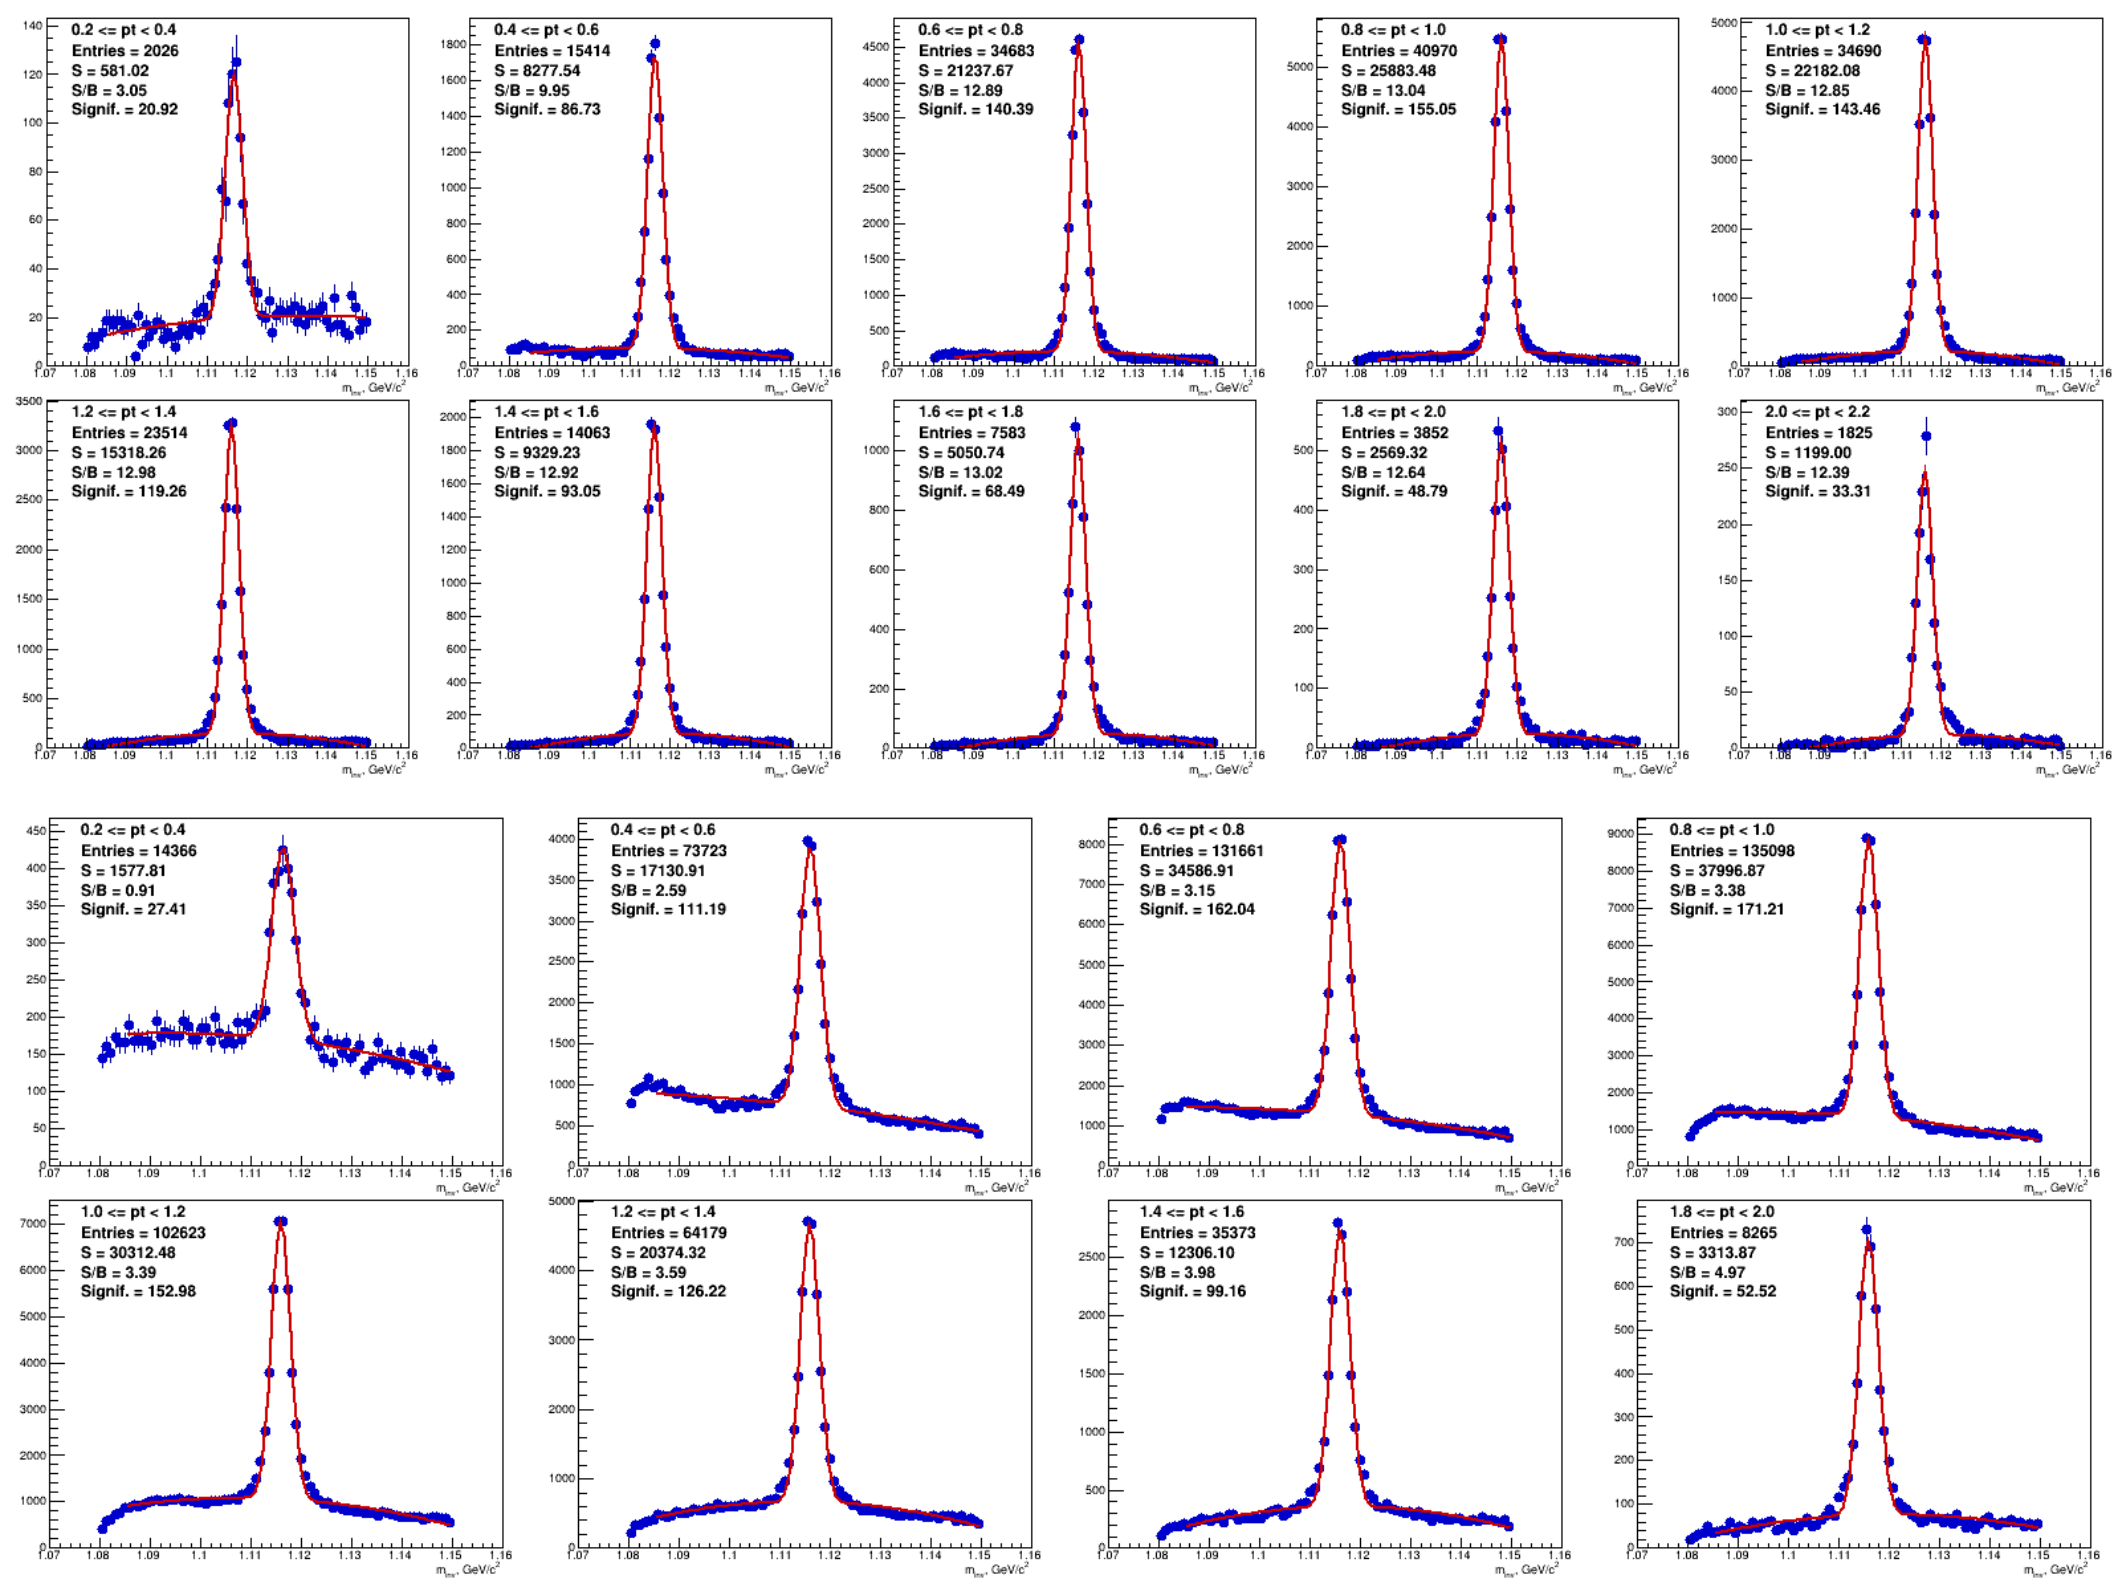

Yields for 10 weeks

Particle	Λ	$\bar{\Lambda}$	Ξ^-	$\bar{\Xi}^+$	Ω^-	$\bar{\Omega}^+$
Expected yield	$5.8 \cdot 10^9$	$7.3 \cdot 10^7$	$2.9 \cdot 10^7$	$1.6 \cdot 10^6$	$1.4 \cdot 10^6$	$2.9 \cdot 10^5$

- * Doing a “worse” Lambda selection with more BG but better efficiency we can gain statistics.
- * Different cuts are needed for various Energy, Centrality, Transverse Momentum for optimal performance.
- * Same 1000 events 277 vs 751 ~ 2.8 times more Lambdas
- * A proper criteria for better efficiency and/or acceptance may be an additional cut selection criteria in addition to those of good S/B or significance
- * But what about bias?

* But what about bias?

UrQMD: AuAu, 2 mil, 11 GeV, 0..16 fm

Old Data (old tpc, tof, hp) with MEPhi Flow code,
Psi = 0, Res = 1 (true flow, no EP reco)

- Charged hadrons are near perfect (as expected)
- But there is some systematic problem with Lambda
- Possible reason
 - systematic bias in cuts for reconstructed Lambda
 - or it may be due to old reconstruction and not present in new data

Latest results

- * UrQMD(non-hydro) 500k events AuAu, 11 GeV, 8..12 fm
- * TPC Clusters, MLEM Finder, PID, Reco Lambda, FHCAL Event Plane, Flow Analysis

On 14.05 started simulation (model, sim, reco) and finished on 06.06
~3-4 weeks for 1 million events, 0..16 fm, on NICA Cluster (50 task limit).
1000 RECO files with 1000 events each.
Accessible at [/nica/mpd15/geraks/sim](#)
Soon to be analysed...

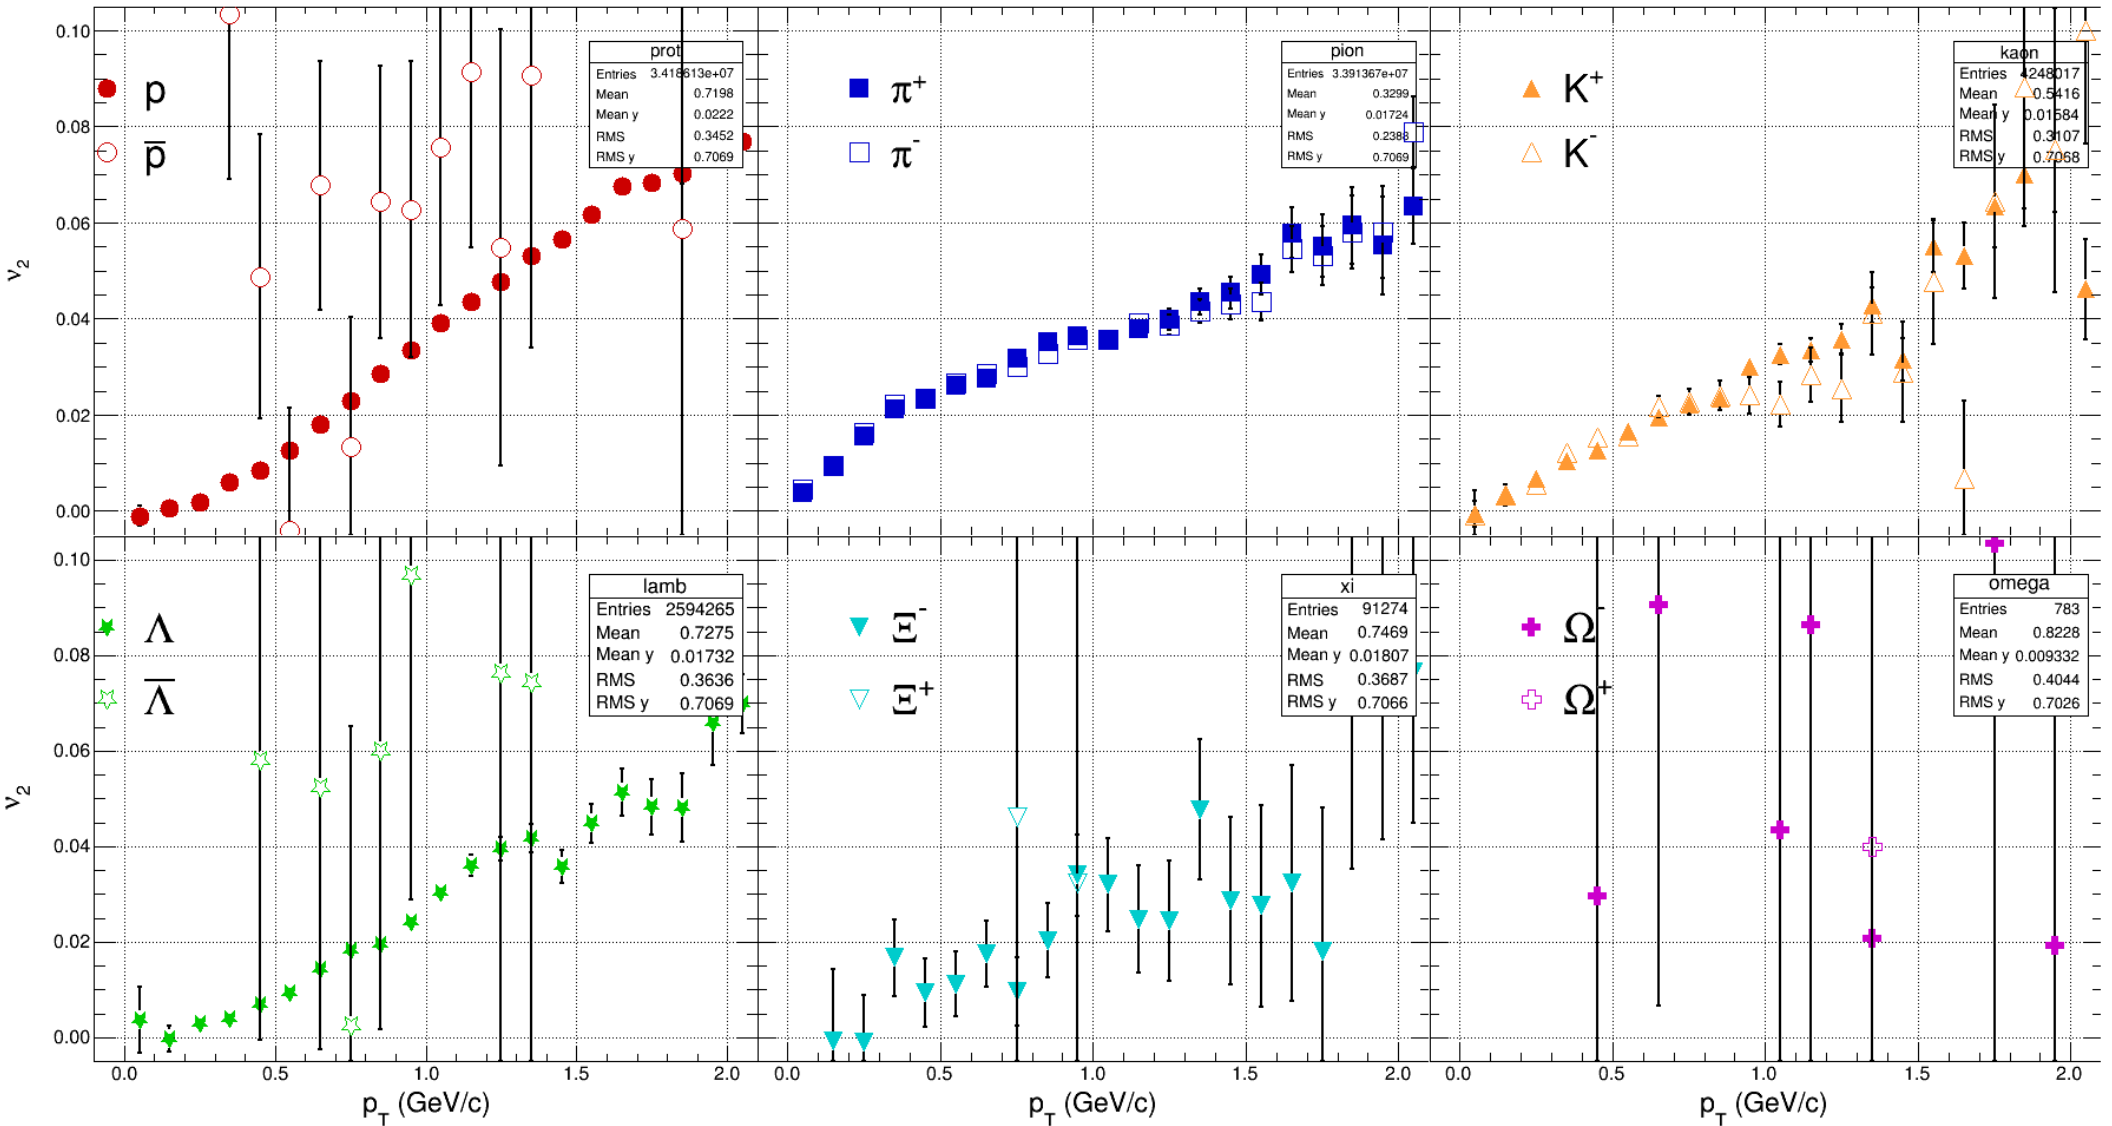

Thank you!
