## The Standard model

The Standard Model (SM): the most fundamental experimentally proven level of understanding of our world we have so far.

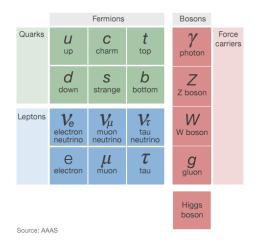

- SM = 3 fermion generations + gauge interactions + Higgs mechanism.
- Gauge group of SM:  $SU(3)_c \times SU(2)_L \times U(1)_Y$  (strong and electroweak interactions).
- The electroweak symmetry of SM is not manifest but broken: Brout-Englert-Higgs mechanism.

Overview of the results

Summary: the LHC surprises

## The problems of the Standard Model

The SM is a minimalistic, fully predictive theory, extremely efficient in describing collider data.

But within the SM, there is:

- something it definitely cannot accommodate (dark matter, efficient baryogenesis);
- something it could accommodate at the price of becoming extremely unnatural;
- something it can describe but not explain.

## There must exist physics Beyond the Standard Model!

We just don't know what it is and at which energy scale it lives.

## Scientific program of the LHC

The main goal of the LHC is to find New Physics.

- tests of the SM at the new energy frontier,
- Higgs boson physics: number of Higgses, their mass, CP-parity, couplings, self-coupling, etc.
- search for various beyond-SM signatures: supersymmetry (SUSY), new gauge interactions, exotic gravity models, dark sectors, etc.
- B-physics as another window into New Physics: study rare B-decays with highest precision,
- + other issues which I don't touch.

#### Accelerator complex at CERN

- cyclic collider: circ. 27 km, nominal proton energy 7 TeV; nominal beam intensity: 2808 bunches with 10<sup>11</sup> p/bunch separated by 25 ns, which gives 300 MJ of beam energy;
- almost 10,000 magnets including 1232 main dipoles holding 11 kA, producing 8.3 T, and storing 10 MJ of energy each;
- Cryo: multi-stage cooling including He-II at 1.9K, heat transport capacity: few kW with the gradient of 0,1 K/km.
- elaborate protection systems (collimators, beam dump, controls), numerous unexpected difficulties (UFO's, electron clouds, ULO, etc.).

Four main detectors: ATLAS and CMS (multi-purpose), LHCb (mostly *B*-physics), ALICE (mostly ion collisions), and several smaller detectors.

#### LHC schedule and luminosity production

Lumi goal:  $10^{34} cm^{-2} s^{-1} \rightarrow 100 \text{ fb}^{-1}/\text{``accelerator year''} (= 10^7 \text{ sec}).$ 

Run 1 (2010–2012): 
$$E_{tot} = 7 \rightarrow 8$$
 TeV.

• ATLAS, CMS: 25 fb<sup>-1</sup>.

Run 2 (2015–2018):  $E_{tot} = 13$  TeV.

- 2015: commissioning year, 3-4 fb<sup>-1</sup>
- 2016–2018: data production, 100 fb<sup>-1</sup>

Run 3 (2021–2023):  $E_{tot} = 14 \text{ TeV}, 300 \text{ fb}^{-1}$ .

Beyond 2025 (up to 2035): HL-LHC, 300 fb $^{-1}$ /year.

# The Higgs boson

Igor Ivanov (CFTP, IST)

LHC at work

Overview of the results

Summary: the LHC surprises

### Higgs mechanism vs. Higgs boson

A key task of the LHC was to find the Higgs boson(s).

- The Higgs mechanism was suggested in 1964 by Brout-Englert, by Higgs, and by Guralnik-Hagen-Kibble. It was the mechanism that was the key development, and the boson was initially just a minor consequence mentioned in 1966.
- The searches began in late 1970's, and every new collider was checking if it can spot the Higgs boson.
- But again: the main interest lies in the Higgs mechanism as it might be the first door to New Physics. Higgs boson is just an "echo of the mechanism", a convenient tool to study it.

Popular misconception: "Higgs boson gives mass to everything in the Universe".

In fact, it is the Higgs <u>field</u> gives mass to <u>fundamental particles</u>  $\rightarrow$  only  $\approx 1\%$  of the mass of the usual matter, and it most probably does not explain the masses of neutrinos and DM.

LHC at work

Overview of the results

Summary: the LHC surprises

#### Two deviations from SM

- *H* → μτ decay. In SM, there is no lepton flavour violating Higgs decays, but they can appear due to New Physics.
   CMS result [1502.07400]: *Br*(*H* → μτ) = (0.84<sup>+0.39</sup><sub>-0.37</sub>)%.
   ATLAS result [1508.03372]: *Br*(*H* → μτ) = (0.77 ± 0.62)%.
   Combined excess: 2.6σ away from SM.
- $t\bar{t}H$  coupling seems to be too strong: CMS [1408.1682]:  $\mu = 2.9^{+1.0}_{-0.9}$ , ATLAS [1503.05066]:  $\mu = 1.5 \pm 1.1$ . Combined excess: 2.3 $\sigma$  away from SM.
- Too early for strong suspicions, but definitely to watch in Run 2.

э

LHC at work

Summary: the LHC surprises

Extremely rare  $B \rightarrow \mu^+ \mu^-$  and  $B_s \rightarrow \mu^+ \mu^-$  decays: a key goal of the LHC *B*-physics program. SM predictions:

 ${
m Br}(B_s o \mu^+ \mu^-) = (3.66 \pm 0.23) \cdot 10^{-9} \,, \; {
m Br}(B o \mu^+ \mu^-) = (1.06 \pm 0.09) \cdot 10^{-10} \,.$ 

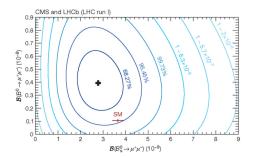

Dramatic year 2011: controversy between Tevatron and LHC  $\rightarrow$  LHC wins.

Overview of the results Summary: the LHC surprises SM and beyond LHC at work  $B_s \rightarrow \mu^+ \mu^-$ : discovery

First hints by LHCb in 2012, evidence by LHCb+CMS in 2013, discovery by LHCb+CMS in 2014.

Current result [1411.4413] = Nature 522, 68 (04 June 2015):

 $B_s \rightarrow \mu^+ \mu^-$  is OK,  $B \rightarrow \mu^+ \mu^-$  is too large, 2.2 $\sigma$  away from SM.

- ₹ ∃ →

< A > . -

LHC at work

Overview of the results

Summary: the LHC surprises

## Semileptonic *B* decays

Several strong deviations in semileptonic B decays:

- LHCb [1512.04442]:  $B \rightarrow K^* \mu^+ \mu^-$ , discrepancy at  $3.4\sigma$ .
- LHCb [1506.08777]:  $B_s \rightarrow \phi \mu^+ \mu^-$ , discrepancy at 3.5 $\sigma$ .
- LHCb [1406.6482]: violation of lepton universality in  $B \to K\ell\ell$ , 2.6 $\sigma$  away from SM,
- LHCb+BaBar+Belle [1506.08896]: violation of lepton universality in  $\bar{B} \rightarrow D^{(*)} \tau \nu$ , ~  $4\sigma$  deviation from SM.

So far, these seem to be the strongest deviations from SM found at the LHC.

However, the interpretation is far from clear. Global analyses of these discrepancies (e.g. in the space of  $C_i$  for  $b \rightarrow s\ell\ell$  decay) show 2–4 $\sigma$  deviation depending on the analysis [1510.04239, 1603.00865].

LHC at work

Overview of the results

Summary: the LHC surprises •00

### After Run 1 + preliminary Run 2

process	deviation	collaboration
$\gamma\gamma$ peak at 750 GeV	$\sim 3\sigma$	ATLAS+CMS
2 TeV dibosons	low	ATLAS+CMS
eejj	$2.8\sigma$	CMS
same sign $\ell$ 's $+b$ 's	$2.5\sigma$	ATLAS
leptons+jets+ $E_T^{miss}$	$2.5\sigma$	CMS
	$2.2\sigma$	ATLAS
$H \rightarrow \tau \mu$	$2.4\sigma$	CMS
Htī	$2.3\sigma$	CMS
$B  ightarrow K^* \mu \mu$	$3.4\sigma$	LHCb
$B_s  o \phi \mu \mu$	$3.5\sigma$	LHCb
$B  ightarrow \mu^+ \mu^-$	$2.2\sigma$	LHCb+CMS
$B^+  ightarrow K^+ \ell \ell$	$2.6\sigma$	LHCb
$B  ightarrow D^{(*)}  au ar{ u}$	$2.1\sigma$	LHCb
	$\sim 4\sigma$	$LHCb{+}BaBar{+}Belle$
