Pygmy and giant dipole resonances in 48,50 Ca and 68,70 Ni

Wednesday, 17 July 2019 15:00 (20 minutes)

The structure of exotic neutron-rich nuclei is one of the main science drivers in contemporary nuclear physics research. An attention has been devoted to effects of varying the ratio between the proton Z and neutron N numbers on different nuclear structure characteristics of nuclei deviated from their valley of β -stability. One of the phenomena associated with the change in N/Z ratios is the pygmy dipole resonance (PDR) [1]. One of the successful tools for describing the PDR is the quasiparticle random phase approximation (QRPA) with the self-consistent mean-field derived from Skyrme energy density functionals (EDF) [2]. Such an approach can describe the properties of the low-lying states reasonably well by using existing Skyrme interactions. Due to the anharmonicity of the vibrations there is a coupling between one-phonon and more complex states [3]. The main difficulty is that the complexity of calculations beyond standard QRPA increases rapidly with the size of the configuration space, and one has to work within limited spaces. Using a finite rank separable approximation for the residual particle-hole interaction derived from the Skyrme forces one can overcome this numerical problem [4-6].

In the present report, we analyze the effects of phonon-phonon coupling (PPC) on the E1 strength distributions of neutron-rich calcium and nickel isotopes. Using the same set of the EDF parameters we describe available experimental data for 48 Ca, 68 Ni and give prediction for 50 Ca, 70 Ni. The inclusion of the PPC results in the formation of low energy 1^- states of 48 Ca. There is an impact of the PPC effect on low-energy E1 strength of 48 Ca [7]. The effect of the low-energy E1 strength on the electric dipole polarizability is discussed. We predict a strong increase of the summed E1 strength below 10 MeV (12 MeV), with increasing neutron number from 48 Ca (68 Ni) till 50 Ca (70 Ni) [8].
