Rare FCNC decays in the Standard Model

Dmitri Melikhov

SINP, Moscow State University & HEPHY, Austrian Academy of Sciences, Vienna

Rare B-decays induced by flavour-changing neutral currents (FCNC) is one of the promising candidates for probing physics beyond the Standard model. However, for identifying potential new physics from the data, reliable control over QCD contributions is necessary. I focus on one of such QCD contributions - the charming loops that provide difficulties in disentangling new physics and discuss the possibility to gain control over them.

1. Motivation: tensions with SM predictions in FCNC $b \rightarrow s, d$ decays
2. $H_{\text{eff}}$ for $b \rightarrow s, d$ and the $\langle \gamma l^+ l^- | H_{\text{eff}} | B \rangle$ amplitude
3. Charming loops
4. Conclusions and outlook
FCNC $b \to s$ and $b \to d$ transitions do not occur at the tree level in SM and proceed via loops. As the result, BRs of FCNC decays are small; on the other hand, new particles may show up virtually in the loops. Therefore, FCNC decays are most popular candidates for indirect search of physics BSM.

Tensions between SM predictions and observations in FCNC $b \to s$ transitions:

In SL decays:

- \[ R_K = \frac{\mathcal{B}(B^+ \to K^+ \mu^+ \mu^-)}{\mathcal{B}(B^+ \to K^+ e^+ e^-)} = 0.745^{+0.090}_{-0.074} \text{(stat)} \pm 0.036 \text{(syst)} \ (2.6\sigma) \text{ range of } q^2 = [1, 6] \text{ GeV}^2; \]

- \[ \mathcal{B}(B^+ \to K^+ \mu^+ \mu^-)_{\text{SM}} = (1.75^{+0.60}_{-0.29}) \times 10^{-7}; \]
  \[ \mathcal{B}(B^+ \to K^+ \mu^+ \mu^-)_{\text{exp}} = (1.19 \pm 0.03 \pm 0.06) \times 10^{-7} \text{ range of } q^2 = [1, 6] \text{ GeV}^2. \]

- \[ R_{K^*0} = 0.69^{+0.11}_{-0.07} \text{ (stat)} \pm 0.05 \text{ (syst) for } q^2 = [1, 6] \text{ GeV}^2 \]

- Same for \( \mathcal{B}(B^+ \to \phi \mu^+ \mu^-) \ (> 3\sigma) \)

In leptonic decays:

- \[ \frac{\mathcal{B}(B_s^0 \to \mu^+ \mu^-)_{\text{exp}}}{\mathcal{B}(B_s^0 \to \mu^+ \mu^-)_{\text{SM}}} = 0.76^{+0.20}_{-0.18} \ (1.2\sigma) \]

Expectations for radiative leptonic decays:

- \[ \frac{\mathcal{B}(B_s^0 \to \ell^+ \ell^- \gamma)}{\mathcal{B}(B_s^0 \to \ell^+ \ell^-)} \sim \left( \frac{M_{B_s^0}}{m_\ell} \right)^2 \frac{\alpha_{\text{em}}}{4\pi} \sim 1 \text{ for muons.} \]
Effective Hamiltonian for FCNC $B -$ decays

At the tree level, the SM allows the following transitions between quarks:

- **charged current transitions** $b \rightarrow W^- q, q = u, c, t$
- **neutral current transitions**: $b \rightarrow b\gamma, b \rightarrow bZ^0$.

FCNC transitions $b \rightarrow s, d$ are forbidden in SM at the tree level, and proceed via loops (boxes and penguins).

- **Example**: $b \rightarrow s\gamma$ vertex

\[ V_{ub} \bar{u} W^- b + V_{cb} \bar{c} W^- b + V_{tb} \bar{t} W^- b = 0 \]

**CKM Unitarity**: $V_{us}^* V_{ub} + V_{cs}^* V_{cb} + V_{ts}^* V_{tb} = 0$

Important feature: due to CKM unitarity, leading UV divergences cancel (GIM mechanism).
• Example: $b \rightarrow s l^+ l^-$ vertex

$\gamma \rightarrow W l l$ + $l^−$ vertex

In the loops heavy and light particles propagate. For the description of $B$-decays, much heavier particles $W, Z, t$ may be “integrated out”. Example for $b \rightarrow s \gamma$:

The contribution of heavy degrees of freedom is described in terms of the effective Hamiltonian

$$\mathcal{H}_{\text{eff}}^{b \rightarrow s} = \frac{G_F}{\sqrt{2}} V_{tb} V_{ts}^* \sum_i C_i(\mu) O_i(\mu),$$

$O_i(\mu)$ - operators; $C_i(\mu)$ - WC, $\mu_0 = 5$ GeV: $C_7(\mu_0) = 0.312$, $C_9V(\mu_0) = -4.21$, $C_{10A}(\mu_0) = 4.64$.

Contributions of top and $W$ to $\mathcal{H}_{\text{eff}}$:

$$\mathcal{H}_{\text{eff}}^{b \rightarrow s l^+ l^-} = \frac{G_F \alpha_{\text{em}}}{\sqrt{2}} \frac{V_{tb} V_{ts}^*}{2\pi} \frac{C_7(\mu)}{q^2} \cdot \bar{s} \gamma_\mu q \gamma^\nu (1 + \gamma_5) b \cdot \bar{\ell} \gamma^\mu \ell +$$

$$+ \ C_9V(\mu) \cdot \bar{s} \gamma_\mu (1 - \gamma_5) b \cdot \bar{\ell} \gamma^\mu \ell + C_{10A}(\mu) \cdot \bar{s} \gamma_\mu (1 - \gamma_5) b \cdot \bar{\ell} \gamma^\mu \gamma_5 \ell]$$
Don’t forget:

$b, c, u, d, s$-quarks are dynamical!

To calculate any amplitude of $B$-decay, one needs to calculate the amplitude of $H_{\text{eff}}$ (describes top and $W$, and $Z$) and add contributions of loops with dynamical light degrees of freedom (masses $\ll M_W$).

In the following I concentrate on $B \rightarrow \gamma l^+ l^-$ decays.

$\langle \gamma l^+ l^- | H_{\text{eff}} | B \rangle + \text{add contributions of } c \text{ and } u \text{ quarks.}$
Top – quark contributions

We need to calculate \( \langle \gamma l^+ l^- | H_{\text{eff}} | B \rangle \) with

\[
H_{\text{eff}}^{b \rightarrow s l^+ l^-} = \frac{G_F \alpha_{\text{em}}}{\sqrt{2} 2\pi} V_{tb} V_{ts}^* \left[ -2i m_b \frac{C_7 \gamma(\mu)}{q^2} \cdot \bar{s} \sigma_{\mu\nu} q^\nu (1 + \gamma_5) b \cdot \bar{\ell} \gamma^\mu \ell + C_9 V(\mu) \cdot \bar{s} \gamma_\mu (1 - \gamma_5) b \cdot \bar{\ell} \gamma^\mu \gamma_5 \ell \right]
\]

The \( \langle \gamma l^+ l^- | H_{\text{eff}} | B \rangle \) amplitude can be parameterized via form factors:

\[
\langle \gamma(k, \epsilon) | \bar{s} \gamma_\mu \gamma_5 b | B_s(p) \rangle = i e \epsilon^*_\alpha \left( g_{\mu\alpha} p k - p_\alpha k_\mu \right) \frac{F_A(k'^2, k^2)}{M_B},
\]

\[
\langle \gamma(k, \epsilon) | \bar{s} \gamma_\mu b | B_s(p) \rangle = e \epsilon^*_\alpha \epsilon_{\mu\alpha\xi\eta} p_\xi k_\eta \frac{F_V(k'^2, k^2)}{M_B},
\]

\[
\langle \gamma(k, \epsilon) | \bar{s} \sigma_{\mu\nu} \gamma_5 b | B_s(p) \rangle (p - k) = e \epsilon^*_\alpha \left[ g_{\mu\alpha} p k - p_\alpha k_\mu \right] F_{TA}(k'^2, k^2),
\]

\[
\langle \gamma(k, \epsilon) | \bar{s} \sigma_{\mu\nu} b | B_s(p) \rangle (p - k) = i e \epsilon^*_\alpha \epsilon_{\mu\alpha\xi\eta} p_\xi k_\eta F_{TV}(k'^2, k^2).
\]

\( k' \) momentum emitted from the FCNC vertex \( b \rightarrow s \) (\( k'^2 \) - first variable of the ffs)

\( k \) momentum emitted from the e.-m. vertex (\( k^2 \) - second variable of the ffs)

Electromagnetic gauge invariance imposes rigorous constraints on the form factors:

\[
F_{TA}(0, q^2) = F_{TV}(0, q^2), F_{TA}(0, 0) = F_{TV}(0, 0)
\]

but

\[
F_{TA}(q^2, 0) \neq F_{TV}(q^2, 0).
\]
• Diagrams with *real* photon emission from valence quarks are described via $F(q^2, 0)$ (no poles in the range $0 < q^2 < M_B^2$: poles in $q^2$ appear at $q^2 = M_R^2$):

![Diagrams with real photon emission](image)

• Diagrams with *virtual* photon emission from valence quarks are described by $F(0, q^2)$ (in the first diagram pole in the physical $q^2$-range):

![Diagrams with virtual photon emission](image)

• Bremsstrahlung ($\sim C_{10A}$)

![Bremsstrahlung](image)

Dashed blob: penguin operator $O_{7\gamma}$; full blob: four-fermion operators $O_{9V}$ and $O_{10A}$. 
A schematic calculation of some of the contributions in “QCD”:

\[ F(q^2, q'^2) = \int dx e^{i q x} \langle 0| T(\bar{b}(x)s(x), \bar{s}(0)s(0))|B_s(p)\rangle = \int dx e^{i q x} dk e^{-i k x} \frac{\langle 0| \bar{b}(x)s(0)|B_s(p)\rangle}{m_s^2 - k^2 - i0}. \]

\[ p = q + q' \quad \text{and} \quad p^2 = M_B^2. \] \( B \)-meson 2DA depends on 2 variables \( x^2 \) and \( xp \)

\[ \langle 0| \bar{b}(x)s(0)|B_s(p)\rangle = \int_0^1 d\xi e^{-ipx\xi} \left\{ \phi_0(\xi) + x^2 \phi_1(\xi) + \ldots \right\} \]

- The LC contribution \( x^2 = 0 \) is easy

\[ F(q^2, q'^2) = \int \frac{dx e^{i q x} \phi_0(\xi) \xi e^{-i p x \xi} e^{-i k x} dk}{m_s^2 - k^2 - i0} = \int_0^1 \frac{d\xi \phi_0(\xi)}{m_s^2 - (q - \xi p)^2} \]

Taking into account that \( (p - q)^2 = q'^2 \), and thus \( 2qp = p^2 - q^2 - q'^2 \), we obtain

\[ k^2 = q^2(1 - \xi) - \xi(1 - \xi)M_B^2 + q'^2\xi. \] Important: \( \phi_0(\xi) \) is peaked near \( \xi \sim \Lambda_{QCD}/m_b \), so \( k^2 \sim -\Lambda_{QCD}m_b \).

The propagating quark is highly virtual, so perturbative expression for its propagator is ok.

\[ F(q^2, q'^2) = \int_0^1 \frac{\phi_0(\xi) d\xi}{m_s^2 - (q^2(1 - \xi) - \xi(1 - \xi)M_B^2 + q'^2\xi)} \]

- \( x^2 \) terms in 2DA: write \( x_\alpha = -i \partial_\alpha e^{ikx} \), parts integration. \( x^2 \rightarrow \Lambda_{QCD}/m_b \) compared to LC term.

Constructions to \( F(q^2, q'^2) \) from powers of \( x^2 \) in 2DA are suppressed.
Charm – loop contributions

Illustration: \[ B \rightarrow K l^+ l^- \] decay \[ 0 < \sqrt{s} < (M_B - M_K) \], \( s \) - momentum squared of \( l^+ l^- \) pair.

- Charmonia appear in the kinematical decay region. In the charmonia region, charm contribution dynamically enhanced and dominates.

- Far from the charmonia region, top dominates (black dashed). Still, to study possible NP effects, Need to gain theoretical control over charm contributions
Charm generates two different topologies: (a) penguin topology (b) weak annihilation topology

(a) \hspace{1cm} (b)

- Account of hard gluon exchanges lead to the four-quark operators

\[
H_{\text{eff}}^{b \to \bar{s} c} = -\frac{G_F}{\sqrt{2}} V_{cb} V_{cs}^* \{ C_1(\mu) O_1 + C_2(\mu) O_2 \}
\]

with

\[
O_1 = \bar{s}^i \gamma_\mu (1 - \gamma_5) c^j \bar{c}^i \gamma^\mu (1 - \gamma_5) b^j, \quad O_2 = \bar{s}^i \gamma_\mu (1 - \gamma_5) c^j \bar{c}^i \gamma^\mu (1 - \gamma_5) b^j,
\]

and the similar terms with \( c \to u \) (\( i, j \) color indices). The SM Wilson coefficients at the scale \( \mu_0 = 5 \) GeV [corresponding to \( C_2(M_W) = -1 \)]: \( C_1(\mu_0) = 0.241, C_2(\mu_0) = -1.1 \).

These operators lead to factorizable contributions to the amplitudes of exclusive FCNC \( B \)-decays.

- Soft gluon exchanges between the charm-quark loop and the \( B \)-meson loop lead to nonfactorizable contributions to the amplitudes.

Nonfactorizable charm contributions are comparable with factorizable contributions

How do we know that? Compare charmonia in $l^+l^-$-annihilation and in FCNC $B$-decays:

The patterns of charmonia in charm contribution to vacuum polarization (left) and in $B \rightarrow K l^+ l^-$ (right) are different. The difference is due to nonfactorizable contributions.

- In some cases, factorizable charm contribution vanishes and thus only nonfactorizable charm contributes (e.g in $B \rightarrow K^* \gamma$)

We need formalism to calculate nonfactorizable charm effects in QCD.
Factorizable part

Product of $B \to \gamma$ form factor and the charm polarization function.
At $q^2 \ll 4m_c^2$, the charm loop may be calculated in pQCD, and has been measured in a broad range of $q^2$. 
Nonfactorizable part (illustration for scalar “quarks” and scalar “gluon”)

\[
A(q, p) = \frac{1}{(2\pi)^8} \int \frac{dk}{m_s^2 - k^2} \int dy e^{-i(k-p'y)} \int dx e^{-ikx} dk \Gamma_{cc}(\kappa, q) \langle 0 | \bar{s}(y) G(x) b(0) | B_s(p) \rangle.
\]

- In the charm triangle diagram $\Gamma_{cc}(\kappa, q)$, for $q^2 \ll 4m_c^2$, also external virtualities $\kappa^2 = \omega^2 M_B^2 = O(\Lambda_{QCD}^2)$ and $q^2 = (\omega p - q)^2 \sim -\omega M_B^2$ are far below the $\bar{c}c$ thresholds. Therefore, the charm loop for this kinematics may be calculated in pQCD.

- The 3DA depends on 5 variables $xp, yp, x^2, y^2, xy$ ($p^2 = M_B^2$) and may be parametrized as follows:

\[
\langle 0 | s^+ (y) G(x) b(0) | B_s(p) \rangle = \int d\lambda e^{-i\lambda y} \int d\omega e^{-i\omega x} \Phi(\omega, \lambda) \left[ 1 + O(\Lambda_{QCD}^2 x^2, \Lambda_{QCD}^2 y^2, \Lambda_{QCD}^2 (x - y)^2) \right].
\]

$\Phi(\omega, \lambda)$ is peaked at $\lambda, \omega \sim \Lambda_{QCD}/m_b$ [$b$-quark carries the major part of the $B$-meson momentum].
The contribution of the LC part of the B-meson 3DA $\Phi(\omega, \lambda)$ to $A(q, p)$ is easy to calculate:

$$A(q, p) = \frac{1}{(2\pi)^8} \int \frac{dk}{m_s^2 - k^2} \int dye^{-i(k-p')y} \int dx e^{-ikx} \frac{d\gamma_{cc}(\kappa, q)}{i\kappa} \int d\omega e^{-i\omega p} \Phi(\omega, \lambda)$$

$$\int dx \rightarrow \delta(\kappa + \omega p), \quad \int dy \rightarrow \delta(k + \lambda p - p').$$

and integrate over $\kappa$ and $k$ we get

$$A(q, p) = \int_0^\infty d\lambda \int_0^\infty d\omega \frac{\Phi(\omega, \lambda) \Gamma_{cc}(-\omega p, q)}{m_s^2 - (\lambda p - p')^2}.\frac{1}{m_s^2 - (\lambda p - p')^2}.$$  

- Charm-quark loop:

$$\Gamma_{cc}(\kappa, q) = \frac{1}{8\pi^2} \int_0^1 du \int_0^1 dv \frac{\theta(u + v < 1)}{m_c^2 + 2uvkq - u(1 - u)\kappa^2 - v(1 - v)q^2}.$$  

$\kappa^2 \sim \Lambda_{\text{QCD}}^2$ (gluon is soft as the major part of the $B$-meson momentum is carried by $b$-quark)

$q^2 \ll 4m_c^2$, and

$q'^2 = (q - \omega p)^2 = q^2 - \omega(1 - \omega)M_B^2 - q^2\omega + p'^2\omega = q^2 - \omega(1 - \omega)M_B^2.$

All external momenta squared are far below the $\bar{c}c$ threshold, i.e. charm loop is perturbative.
\begin{itemize}
  
  \item \textit{s}-quark propagator

  \[ m_s^2 - (\lambda p - p')^2 = m_s^2 - \lambda q^2 + (1 - \lambda)(\lambda M_B^2 - p'^2) \sim -\Lambda_{\text{QCD}}m_b. \]

  \textit{s}-quark is highly virtual.

  Contributions of \(x^2\), \(y^2\), \(xy\)-terms in 3DA to the amplitude \(A(q, p)\) relative to the \(\Phi(\omega, \lambda)\) term:

  \[ y_\alpha \rightarrow \frac{k_\alpha}{m_s^2 - k^2} \sim \frac{k_\alpha}{\Lambda_{\text{QCD}}m_b}, \quad x_\alpha \rightarrow \frac{\{q_\alpha, k_\alpha\}}{m_c^2}. \]

  and therefore

  \[ \Lambda_{\text{QCD}}^2y^2 \rightarrow \Lambda_{\text{QCD}}^2 \frac{k^2}{\Lambda_{\text{QCD}}^2m_b^2} \sim \frac{\Lambda_{\text{QCD}}}{m_b}, \]

  \[ \Lambda_{\text{QCD}}^2x^2 \rightarrow \Lambda_{\text{QCD}}^2 \frac{q\kappa}{m_c^4} \sim \frac{\Lambda_{\text{QCD}}^3m_b}{m_c^4}, \]

  \[ \Lambda_{\text{QCD}}^2xy \rightarrow \Lambda_{\text{QCD}}^2 \frac{(p' - \lambda p)(q - \omega p)}{\Lambda_{\text{QCD}}m_b^2m_c^2} \sim \frac{m_b\Lambda_{\text{QCD}}}{m_c^2}. \]

\end{itemize}
Summary for nonfactorizable corrections:

Nonfactorizable corrections are expressed via

\[ \langle 0|s^+(y)G(x)b(0)|B_s(p)\rangle = \int d\lambda e^{-i\lambda y} \int d\omega e^{-i\omega x} \Phi(\omega, \lambda) \left[ 1 + O(\Lambda_{\text{QCD}}^2 x^2, \Lambda_{\text{QCD}}^2 y^2, \Lambda_{\text{QCD}}^2 (x-y)^2) \right], \]

The new recent result is that the knowledge of its functional dependence on \((x-y)^2\) is essential for a proper resummation of large \(\Lambda_{\text{QCD}}m_b/m_c^2\) corrections.

Previously, it was believed that the 3DA with aligned arguments \(x_\mu = uy_\mu\), on the LC \(x^2 = 0, y^2 = 0\) and \((x-y)^2 = 0\) is sufficient to calculate nonfactorizable contributions.

One needs the off-LC contributions. A challenge for future calculations
Form factor calculation

For form factor calculations at $q^2$ below the resonance region, we make use of dispersion approach based on constituent quark picture: All hadron observables are given by dispersion representations in terms of the hadron relativistic wave functions and the spectral densities of Feynman diagrams with constituent quarks in the loops.

- Decay constants:
  \[
  f_{P,V} = \int ds \phi_{P,V}(s) \rho_{P,V}(s)
  \]

- Meson-meson transition form factors:
  \[
  F_{M_1 \to M_2}(q^2) = \int ds_1 \phi_1(s_1) ds_2 \phi_2(s_2) \Delta(s_1, s_2, q^2)
  \]

- Meson-photon transition form factors into photon of virtuality $k^2$:
  \[
  \phi_\gamma(s) = 1/(s - k^2)
  \]

- The wave function is normalized via the electromagnetic form factor at $q^2 = 0$:
  \[
  F_{el}(q^2 = 0) = \text{charge}
  \]
How these form factors agree with the known properties form QCD in different limits?

*The spectral representations:*

- The meson-meson transition form factors satisfy constraints from HQET for heavy-to-heavy transitions
- The meson-meson and meson-photon form factors satisfy constraints from LEET for heavy-to-light transitions

*Fixing numerical parameters:*

- For relativistic wave functions a simple one-parameter Gaussian Ansatz is taken ($k^2$ is the known function of $s$)
  \[ \phi(s) \sim e^{-\frac{k^2}{2\beta^2}} \]
- Constituent quark masses and the parameter of the wave function are fixed by the condition that the known leptonic decay constants of the mesons involved + a few well-measured values of the form factors at large $q^2$ from lattice QCD at large $q^2$. 
• Form factors $F(q^2, 0)$:

(i) Single-pole suggested by LEET, with $F_i(0)$ calculated with our approach:

$$F_i(q^2, 0) = \frac{F_i(0)}{1 - q^2/M_R^2}.$$ 

(ii) Modified pole; parametrizes our results in a broader range $0 < q^2 < 15$ GeV$^2$

$$F_i(q^2, 0) = \frac{F_i(0)}{(1 - q^2/M_R^2)(1 - \sigma_1 q^2/M_R^2 - \sigma_2(q^2/M_R^2)^2)}.$$
• Form factors $F(0, q^2)$:

For subprocesses with resonances in the physical $q^2$-range, we have calculated form factors at $q^2$ below the resonances via dispersion approach. For larger values of $q^2$ we make use of the vector-meson dominance

$$F(0, q^2) = F(0, 0) + q^2 \frac{f_V/M_V}{M_V^2 - q^2 - i\Gamma_V M_V}.$$
Numerical results

Differential distributions in $B \to \gamma l^+ l^-$ vs $q^2 [GeV^2]$.

Light vector resonances and charmonia have completely different origins: Light vector resonances appear as resonance contribution in the same quark loop as $B$-meson (i.e. they contain one valence quark). Charmonia emerge in a different quark loop (after going to effective EW theory).
At large $q^2$ one measures interference of Bremsstrahlung and the part given via the form factors. In the range $q^2 = 16 - 23$ GeV$^2$ there is still a rather strong sensitivity to the $f_f$ $q^2$-dependence.

Measuring the ratio $R(\mu\mu/ee)$ at large $q^2$ directly probes the $q^2$ dependence of the form factors.
Forward-backward asymmetry

$B_s \rightarrow \mu^+\mu^-\gamma$: 

$B_d \rightarrow \mu^+\mu^-\gamma$: 

Conclusions and outlook

- FCNC $B$-decays remain a promising candidate for indirect NP searches. A few tensions with the SM predictions ($B$-physics anomalies) have been observed experimentally.
- Charm provides sizeable contributions to the amplitudes of FCNC decays. In the charmonia regions charm contributions dominate the amplitudes of FCNC $B$-decays. Moreover, nonfactorizable charm effects are comparable in size with factorizable charm effects.
- What happens with the charm contributions beyond the resonance regions, is a serious open theoretical problem in FCNC $B$-decays. According to some estimates, charm contributes to the differential distributions, including the asymmetries, at the level of 5-10% at $q^2$ also far beyond $J/\psi, \psi'$.
- At $q^2 \ll 4m_c^2$, a consistent description of nonfactorizable charming loops requires the knowledge of off-LC 3DAa.
- If charm effects are controlled well, the distributions (in particular, $A_{FB}$) potentially have the sensitivity to the precise values of the Wilson coefficients, i.e. have sensitivity to new physics.
• Including Lorentz structures in the $B$-meson three-particle DA:

In QCD, new functions emerge when one wants to generalize terms of the following type:

$$\langle 0 | \bar{s} (x) G_{\alpha\beta}(ux)b(0)|B(v) \rangle = \int d\lambda e^{-i\lambda x_p} \int d\omega e^{-i\omega u x_p} \left[ \frac{x_\alpha y_\beta}{x v} - \frac{x_\beta y_\alpha}{x v} \right] \Phi(\lambda, \omega).$$

How to generalize them for a non-aligned case? Obviously, new structures and new amplitudes arise:

$$\langle 0 | \bar{s} (y) G_{\alpha\beta}(x)b(0)|B(v) \rangle = \int d\lambda e^{-i\lambda y_v} \int d\omega e^{-i\omega y_v} \times \frac{1}{2} \left[ \left( \frac{x_\alpha y_\beta}{x v} - \frac{x_\beta y_\alpha}{x v} \right) + \left( \frac{x_\alpha y_\beta}{x v} - \frac{x_\beta y_\alpha}{x v} \right) \right] \Phi_S(\lambda, \omega) + \left( \frac{x_\alpha y_\beta}{x v} - \frac{x_\beta y_\alpha}{x v} \right) \Phi_A(\lambda, \omega).$$

$\Phi_S = \Phi$ from (1), whereas $\Phi_A$ is new. If the contributions induced by $\Phi_A$ are not suppressed, a consistent calculation of the decay amplitude $A$ needs further inputs.
Local OPE corresponds to power expansion of \( G(ux) \): \( G(ux) = G(0) + ux_\alpha \partial^\alpha G + \ldots \).

1. The leading contribution comes from \( G(0) \) term:

\[
\langle 0|\bar{s}(y)G(0)b(0)|B(p)\rangle|_{x=0} = \int d\lambda e^{-i\lambda y p} \int d\omega \left[ \Phi(\lambda, \omega) + O(y^2) \right].
\]  

(3)

2. Let us consider the contribution of \( x_\alpha \partial^\alpha G(0) \).

- The \( x_\alpha \) term can be generated by \( \partial^\alpha e^{iqx} \) and after taking the integrals leads to \( \frac{q_\alpha}{m_c^2} \).

- The \( \partial^\alpha G(0) \) term reads

\[
\frac{\partial}{\partial x_\alpha} \langle 0|\bar{s}(y)G(ux)b(0)|B(p)\rangle|_{x=0} = -iup_\alpha \int d\lambda e^{-i\lambda y p} \int d\omega \omega \Phi(\lambda, \omega) + C_2 \Lambda_{QCD} x_\alpha \\
= \frac{C_1 p_\alpha}{m_b} \frac{\Lambda_{QCD}}{m_b} + C_2 \Lambda_{QCD} x_\alpha
\]  

(4)

The term \( C_2 \) arises when the derivative acts on \( x^2 \) and \( xy \) terms in the full off-LC 3DA.

3. The leading part in the ratio of the \( \partial_\alpha G(0) \) over the \( G(0) \) contributions to the amplitude arises when \( q_\alpha \) contracts with the term \( \sim p_\alpha \) and reads

\[
\frac{qp\Lambda_{QCD}}{m_b m_c^2} \sim \frac{M_B\Lambda_{QCD}}{m_c^2} \sim 1.
\]  

(5)

For the realistic case of \( c- \) and \( b \)-quarks, the “suppression” factor is around 1. So no real hierarchy of the contributions within the local OPE. Summation is necessary, this is done by LC OPE.
Can we use “duality” to predict charm contribution in exclusive FCNC $B$-decays?
